The first can be stated concisely, “write ‘01’ 10 times”. The second does not have any method to generate a pattern of digits, hence no expression shorter than the 20 characters of 0 and 1 (not compressible) (Chaitin, Algorithmic, p. 16).

A common criticism is that neither version serves as statistical test for randomness (Eagle, 2005, pp. 11-12).

Predictability and Probability

Probability is not the same as randomness, although it relies on it by describing individuals selected without bias from an “infinite” population (Ramsey, p. 34-35, 39). In essence, if one cannot predict the nature of the next event (done by statistics), then that event is more random. Statistics increases predictability and lessens randomness, assuming that the future resembles the past (Whewell, 1847; Hume; 1888; Keynes, 1921, p. 305-314). A deviation of the expected values in a probability analysis would be considered random. If this observation doesn’t help in making the prediction, the event is said to be “random” (Eagle, 2005):

Entropy

Entropy has numerous definitions but forms a basis of randomness. If everything is uniform, there is no way of distinguishing something. There is no information or ability to say specifically what will happen next. Two main currents of entropy are energy dispersion and lack of information.

A system starts in an ordered state (arrangement according to a scheme) and increasing entropy allows many more possibilities of arrangements, i.e., less ordering. In a closed system, energy is equally dispersed when it attains maximum entropy (Clausius, 1870; Thompson, 1852). Ultimately, inside the final stage of the universe energy will be equally dispersed; there will be no differentiation of objects but only uniformity, an equal probability of occurrence, or randomness (Davies, 1984).

Shannon (1948, p. 393) said that compared to what is predicted in a message, what actually gets through determines entropy. That is, what would be the expected message length a person would need to be to transmit the measured value of a random variable?

Note that randomness is not the same as the more technical “chaotic”, as in chaos theory (Gleick, 1987).

Completeness and Uncertainty

Perhaps the most significant of all aspects of randomness in terms of predictability and certainty was formulated by Heisenberg, i.e.,

We simply cannot know the present in principle in all its parameters. Therefore all perception is a selection from a totality of possibilities and a limitation of what is possible in the future. ... [O]ne could be tempted to conclude that behind the observed, statistical world a “real” world is hidden, in which the law of causality is applicable. We want to state explicitly that we believe such speculations to be both fruitless and pointless. ... Because all experiments are subject to the laws

of quantum mechanics, it follows that quantum mechanics once and for all establishes the invalidity of the law of causality.” (Heisenberg, 1927)

This statement stands on its own, a source of much modern day angst.

Does Randomness Exist?

A major tenet of the ages of Reason and Enlightenment was to banish anything unpredictable as flying in the face of God’s design (Paley, 1881), hence atheistic. For example, Bernoulli said, “Everything that exists or originates under the sun, – the past, the present, or the future, – always has in itself and objectively the highest extent of certainty” (Bernoulli, 1713). In 1718 Abraham De Moivre (Central Limit Theorem – Gaussian curve, or binomial distribution), said one could account for all phenomenon in terms of how likely it would be for it to appear, i.e., degree of certainty, or probability. Like many other natural philosophers of the day, he did not think chance existed; everything was ordered (De Moivre, 1756, p. 253). Einstein said about uncertainty (randomness) that “God does not play dice” (Born, 1926, p. 90-91). Russell was unwilling to give up strict determinism, saying “Where determinism fails, science fails” (Russell, 1996, p.67).

“...[T]rue randomness’ is a mathematical impossibility” (Fiorini, 2014, p. 2). Calude (2015, p. 4) says, “There is no true randomness, irrespective of the method used to produce it”. Then, “Anyone who considers arithmetical methods of producing random digits is, of course, in a state of sin. ... There is no such thing as a random number - there are only methods to produce random numbers, and a strict arithmetic procedure of course is not such a method (Von Neumann, 1951, p. 36)”. Eagle says, “No mathematical definition of random sequence can adequately capture physical randomness” (Eagle, p. 14). Suffice it to say, such statements require one to look closely at terms often used in conjunction with “random”, such as “correlation”, “probability”, “chance”, and uncertainty.

Living With Randomness

Random numbers tables help avoid human bias in selecting samples. Other applications include cryptography, gaming, polling, and scientific experimentation, among many others (Applications of Randomness, 2015). People rely on randomness for uncertainty (bias-free selection). Random numbers sequences may be “true” (unpredictable by anyone and natural, as in radioactive decay), pseudo (unpredictable to one but predictable, to another), and quasi – uniformly distributed sequence of elements (RNG – types, 2015).

Eagle demands for an analysis of randomness:

- Unbiased sampling, as in scientific experimentation and polling;
- Determining if single events are random or not, i.e., “finite randomness”.
- Explaining the behavior of systems, be it purposeful or not. Randomness needs empirical validation (confirmed) or invalidation (disconfirmed);
- Randomness needs to be compatible with determinism, as in processes like population genetics or chaotic dynamics. (Eagle, 2005, pp. 7-8)

Numerous tests for randomness include statistics and complexity analysis (as in Kolmogorov-Smirnov). If a sequence of elements (characters, images, and so forth) passes one or more of these tests, then it is considered “random”, given just the test. Note that these tests are applied to what has been generated. (Tests for Randomness, 2015)

ISSUES

Emergence illustrates a form of induction, where the whole is greater than the sum of the parts. The founder of the journal *Emergence* says “... emergence is appealed to when the configuration of the components of a complex system offers more explanatory insight into the dynamics of the

Table 1. Patterns from randomly concatenated binary formula

(Wolfram, NKS, 2002, p. 170)

(Wuensche, 2015)

system than do explanations based on the parts alone. (Goldstein, 2015, p. 53) Wolfram (2002, p. 170) and Wuensche (2016) show how reputed randomly concatenated individual binary formula produce emerging patterns (here, fractals), as in:

Related to emergence, literature abounds on there being order from a “potential” or chaos (Kauffman; 1988; Gleick, 1994).

A pattern does not necessary mean what we think it represents (e.g., likeness of a person’s face in the clouds), or pareidolia (Pareidolia, 2015). Conversely, regularity appears in some cases to be a function of duration, an issue raised by the tests for randomness. The tests are performed on what has been generated, but long-term there might be regularity (or not - “pseudo order”). The study of statistics is based on the future resembling the past, one of Hume’s problems of induction.

Everything is apprehended in terms of what it is not, randomness being no exception. (dialectics). Reputable scientific institutions do not seem to hesitate in accepting that “...randomness is the opposite of order, the absence of pattern. “(MIT, 2016), but what is order?

Binary (propositional) logic is the foundation of the machine language used by computers but also represents the innate structure of the universe (Horne, 1997, 2012, 2015). At Planck Scale, no solidness exists, or at least anything that would remain in the same place (Heisenberg, 1983), but here are the fundamental and binary building blocks of the universe represented by two variables (Misner, 1973, p. 1235 et. seq.; Piaget, 1958;

Digital Physics, 2015; Wheeler, 1990, p. 5), the universe and a background into which something flicks in and out of existence (Hawking, 2015). This is where order meets randomness, one in terms of the other. In the quantum-cosmological arena, our universe stemmed from a singularity, uniformity. Here, the singularity dialectically existed either in terms of a “nothing” or another universe, or world.

Deductive systems may represent order, as in propositional logic, but ultimately, as Gödel (1931) indicated, there is incompleteness. One may ask simply what was used to construct the systems. Once someone points to an axiom, proposition, rule, etc. it may be asked what gave rise to these, ad infinitum. Conventions are only stopgaps (Horne, 1997).

Radioactive decay, Brownian movement, and “white noise” are random but these could follow some regularity which simply is unknown to us. In logic, there is the fallacy of *argumentum ignoratum*, or the fallacy from ignorance (Fallacy of Ignorance, 2016). Because one has not encountered an entity (a pattern), it does not mean that the entity does not exist.

Randomness inextricably involves time, at least what we think of time, assuming that it exists at all. If modern physicists are correct, time may be an illusion (Aaron, 2013). Einstein said that time is relative, each person having their own time. It is conceivable that from a distant part of the universe, one may be able to see our future, meaning that may have been determined, hence predictable in some way. Like time, then, predictability would be relative.

Finally, from a second order cybernetics [recursive] (Heylighen and Joslyn, 2001) perspective, one may ask whether this chapter is compressible; indeed it just may be random (☺).

FUTURE RESEARCH DIRECTIONS

Work should proceed in these areas. Randomness is tied to determinism, and determinism is about

free will. If everything is predetermined one may disregard making ethical choices. Social cohesion may rely on acting *as though* there were free will. We may act as though there were randomness, similar to that of doing a logic proof in drawing an assumption line and displaying the consequences.

There always is a persuasive idea that we are someone’s idea, analogous to a computer program (Bostrom, 2003). The question then arises about randomness is that world, even though we are predetermined.

Astrophysicists have determined that the universe is tending towards disorder, a heat death, all energy being equally dispersed, or a state of maximum entropy (Davies, 1984). Randomness, it seems will have its final say, winning out over order. However, this may not be the final word, if Hawking and others are correct about there being other universes and the possibility that ours in its end state may become a part of another dimension. Coupled with this is the recent speculation about black holes as portals into other worlds with other dimensions, i.e., as Hawking (2016) states, “Things can get out of a black hole, both to the outside, and possibly, to another universe.”

CONCLUSION

By no means has this chapter given complete treatment of randomness. Too, ours has been a Western orientation, not accounting adequately for East Asian views (Hinduism and Buddhism, for example). A case has been made for the opposite of random, order.

Investigators rely on generating a series of unexpected events that are given designations, such as numbers or letters, to identify what will be used to select members of a sample, scramble messages, or in simulating events in a model (among various uses). The ontology of randomness is reduced to discussing whether uncertainty is innate in the universe. Can what gives rise to Heisenberg-type uncertainties, the core of “natural randomness” ultimately be predicted? For now,

the answer appears to be “no”, but so were time and space thought to be absolute prior to Einstein. Physics (as expressed by its laws) (Feynman, 2001), like reputedly deductive systems is incomplete (Gödel, 1931), or something is missing or uncertain (Heisenberg, 1983). The uncertainty that we observe can produce emergence, or order that cannot be accounted for by the pieces that to us are assembled randomly.

Randomness has two aspects, with regularity, or uniformity, pursuing us in two domains, one of object and one of process. As an object, one thinks of Boltzmann, Clausian entropy, energy being dispersed evenly, with no distinction between one space-time coordinate and the next. The universe will die a heat death, in this way. Or we can think of the integrity of information, both by content (as in Kolmogorov-Chaitin compression) or integrity of transmission (Shannon, 1948). The second aspect is the regularity of process; the method of arriving at a conclusion is uniform, the future resembles the past, and the way of understanding these is the same: logic, unbiased and equally distributed sampling, scientific methods, replication, and so forth.

There is a parallel process within regards to knowledge. Knowledge acquisition comes through synthesis and analysis, the former being the assemblage of pieces to make a whole, the latter the subdivision of the whole into pieces, a process formalized by Descartes, who said, “... we cannot conceive body unless as divisible” (Descartes, 1641). At some point a subdivided world of knowledge may have such a small granularity of detail that one idea is no more significant than the next, a common complaint being an “information glut”. Too, knowledge is analogous to energy entropy, where once emitted cannot be “un-emitted”. Then, there is uniformity as a process that allows the experimental scientific method (Whewell, 1841). $E=MC^2$ says energy is known because of “matter” (material) and vice versa. Analogously, there is the duality of uniformity – process in terms of material and vice versa. Ultimately the ontology

of randomness (in all its aspects of entropy, uncertainty, and lack of prediction) is existence in terms of order, the dialectics of something being in terms of what it is not.

KEY TERMS AND DEFINITIONS

Cartesianism: Repeated subdivision; reductionism.

Chance: Unexpected happening without regard to any other phenomenon or explanation.

Complexity: Amount and detail of intricacy, often expressed in the most reduced or abbreviated form.

Compressibility: Ability to produce the same essence of content in a reduced or compacted manner.

Deduction: In logic, if the premises are true, the conclusion is guaranteed. Closed systems.

Epistemology: A study of what exists.

Entropy: Either a dispersal of energy (Clausius) or loss of information integrity (Shannon).

Induction: In logic, the degree of probability that a conclusion will follow from the premises. Open systems.

Ontology: The study of what exists.

Probability: An inductive form of analysis by assessing the degree of certainty of future events, obtained by observing and analyzing an unbiased population sample.

Random: Uncertain; unpredictable; not having any method or algorithm to produce a phenomenon.

Scientific Method: Extrapolating from the past to project to the future.

Statistics: A form of computable induction, deciding the degree of certainty of future events.

Order Statistics and Applications

E. Jack Chen
BASF Corporation, USA

INTRODUCTION

Order statistics refer to the collection of sample observations sorted in ascending order and are among the most fundamental tools in non-parametric statistics and inference. Statistical inference established based on order statistics assumes nothing stronger than continuity of the cumulative distribution function of the population and is simple and broadly applicable. Important special cases of order statistics are the minimum and maximum value of samples, the sample median and other sample quantiles. Order statistics have been widely studied and applied to many real-world issues. It is often of interest to estimate the reliability of the component/system from the observed lifetime data. In many applications we want to estimate the probability that a future observation will exceed a given high level during some specified epoch. For example, a machine may break down if a certain temperature is reached. For more applications of order statistics, see (Arnold et al., 2008; David & Nagaraja, 2003; DasGupta, 2011).

It is the purpose of this chapter to present some of the more important results in the sampling theory of order statistics and of functions of order statistics and their applications, such as tests of independence, tests of goodness of fit, hypothesis tests of equivalence of means, ranking and selection, and quantile estimation. Order-statistics techniques continue to be key components of statistical analysis. For example, quantile estimates are used to build empirical distributions, tests of goodness of fit are used to check the validity of the fitted input distribution, hypothesis tests of equivalence of means, and ranking and selection procedures are used to compare the performance of multiple systems.

BACKGROUND

Let $X_i, i = 1, 2, \dots, n$, denote a sequence of mutually independent random samples from a common distribution of the continuous type having a probability density function (pdf) f and a cumulative distribution function (cdf) F . Let $X_{[u]}$ be the u^{th} smallest of these X_i such that $X_{[1]} \leq X_{[2]} \leq \dots \leq X_{[n]}$. Then $X_{[u]}, u = 1, 2, \dots, n$, is called the u^{th} order statistic of the random sample $X_i, i = 1, 2, \dots, n$. Note that even though the samples $X_1, X_2, \dots, X_n$ are independently and identically distributed (iid), the order statistics $X_{[1]}, X_{[2]}, \dots, X_{[n]}$ are not independent because of the order restriction. The difference $R = X_{[n]} - X_{[1]}$ is called the sample range. It is a measure of the dispersion in the sample and should reflect the dispersion in the population.

Suppose $U_1, U_2 \sim U(0, 1)$, where “ $\sim$ ” denotes “is distributed as” and “ $U(a, b)$ ” denotes a uniform distribution with range $[a, b]$. We are interested in the distribution of $U_{[2]} = \max(U_1, U_2)$, which can be viewed as the second order statistic. The cdf of $U_{[2]}$ is

$$\begin{aligned} F(x) &= P(\max(U_1, U_2) \leq x) \\ &= P(U_1 \leq x, U_2 \leq x) \\ &= P(U_1 \leq x)P(U_2 \leq x) \\ &= x^2 \end{aligned}$$

Furthermore, the cdf of $U_{[1]} = \min(U_1, U_2)$, which can be viewed as the first order statistic, is

$$\begin{aligned}
 F(x) &= 1 - P(\min(U_1, U_2) > x) \\
 &= 1 - P(U_1 > x)P(U_2 > x) \\
 &= 1 - (1 - x)^2
 \end{aligned}$$

Consider a device contains a series of two identical components and the lifetime of the component $L_c \sim U(0,1)$. If any of these two components fail, the device fails, such as chains. Then, the lifetime of the device $L_d \sim \min(L_{c1}, L_{c2})$. On the other hand, if these two components are configured in parallel and the device fails only when both components fail, such as a strand contains a bundle of threads. Then the lifetime of the device $L_d \sim \max(L_{c1}, L_{c2})$. These techniques can be used in reliability analysis to estimate the reliability of the component/system from the observed lifetime data.

When there are more than two samples, the distributions of sample minimum and sample maximum can be obtained via the same technique. However, the u^{th} ($u \neq 1$ and $u \neq n$) order statistic needs to be obtained via other techniques. Similarly, joint distributions of order statistics and conditional distributions of order statistics require more complicated derivation.

MAIN FOCUS

We discuss distributions of order statistics, joint and conditional distributions of order statistics, and empirical distribution functions and show how order statistics techniques are used in statistical analysis. We then present several procedures that are derived based on inference of order statistics, e.g., tests of independence, range statistics and hypothesis tests of equivalence of means, ranking and selection procedures, and quantile estimation.

Distributions of Order Statistics

Hogg et al. (2012) show that the distribution of the u^{th} order statistic of n samples of X (i.e., $X_{[u]}$) is

$$g_{u:n}(x) = \beta(F(x); u, n - u + 1) f(x),$$

where

$$\beta(x; a, b) = \frac{(a + b - 1)!}{(a - 1)!(b - 1)!} x^{a-1} (1 - x)^{b-1}.$$

That is,

$$g_{u:n}(x) = n! \frac{[F(x)]^{u-1} [1 - F(x)]^{n-u}}{(u-1)!(n-u)!} f(x).$$

Furthermore, the cdf

$$G_{u:n}(y) = \int_{-\infty}^y g_{u:n}(x) dx.$$

In particular, the first order statistic, or the sample minimum, $X_{[1]}$ has the pdf

$$g_{1:n}(x) = n[1 - F(x)]^{n-1} f(x)$$

and the cdf

$$G_{1:n}(x) = 1 - [1 - F(x)]^n.$$

The n^{th} order statistic, or the sample maximum, $X_{[n]}$ has the pdf

$$g_{n:n}(x) = n[F(x)]^{n-1} f(x)$$

and the cdf

$$G_{n:n}(x) = [F(x)]^n.$$

In the cast that f is the uniform $[0,1]$ distribution,

$$g_{u:n}(x) = \beta(x; u, n - u + 1).$$

That is, let $U = x \sim U(0, 1)$, then the random variate $y = \beta(U; u, n - u + 1)$ is the u^{th} order statistic of n random variables with uniform $[0, 1]$ as the parent distribution. From this we can deduct that

$$E[X_{[u]}] = \frac{u}{n+1},$$

and

$$\text{Var}[X_{[u]}] = \frac{u(n-u+1)}{(n+1)^2(n+2)}.$$

This result can be used in simulation to generate the u^{th} order statistic of any variates with a strictly increasing cdf. A straightforward way of simulating order statistics is to generate a pseudo-random sample from the distribution F and then sort the sample in ascending order. This general method requires sorting and can be avoided by using the process below. Based on the fact that $y = F(x) \sim U(0, 1)$, we generate a random variate $y = \beta(U; u, n - u + 1)$ and return the value $x = F^{-1}(y)$ as the u^{th} order statistic with parent distribution F . Here F^{-1} is the inverse distribution function (or quantile function) and is defined by

$$F^{-1}(y) = \inf \{x : F(x) \geq y\}.$$

In the case that F is uniform $[0, 1]$, $y = F^{-1}(y)$. For more information of using inverse transform to generate random variates, see (Law, 2014).

For any $0 < p < 1$, the $100p^{\text{th}}$ percentile (or p quantile) is the value such that about $100p\%$

of the observations are less than or equal to this value and $100(1-p)\%$ of the observations are larger. For example, the median is the 0.5 quantile, i.e., half of the observations are less than or equal to the median and one-half are greater. The median is a measure of location that is considered an alternative to the mean. Sample median (quantile) is a natural estimator of the population median (quantile) of the distribution and can be obtained from order statistics. The order statistics p quantile estimator is the u^{th} ($u = np$) order statistic, i.e., $X_{[u]}$, where z is the smallest integer that is greater than or equal to the real number z . Hence, np of the observations are less than or equal to $X_{[u]}$. One advantage of the sample median over the sample mean is that it is less sensitive to extreme observations. Note that if $U_1, U_2, \dots, U_n$ are iid $U(0, 1)$ random variables and $X_1, X_2, \dots, X_n$ are iid random variables with common distribution F such that $X_i = F^{-1}(U_i)$, then $X_{[i]} = F^{-1}(U_{[i]})$.

A properly selected set of quantiles can reveal all the essential distributional features of random variables being analyzed. Furthermore, in many situations, quantiles provide more useful information than the mean and variance. For example, to ensure the inventory is able to satisfy customers' demands 95% of the time, the stock should be the 0.95 quantile of the distribution of the demand; which can be estimated by the 0.95 sample quantile (i.e., the $0.95n^{\text{th}}$ order statistic of n observations).

Joint and Conditional Distributions of Order Statistics

The joint density function of $(X_{[u]}, X_{[v]})$, $1 \leq u < v \leq n$ is denoted by $g_{u,v:n}(x, y)$. It can be shown that

$$g_{u,v;n}(x,y) = n! \frac{[F(x)]^{u-1} [1-F(y)]^{n-v}}{(u-1)! (n-v)!} \frac{[F(y)-F(x)]^{v-u-1}}{(v-u-1)!} f(x)f(y).$$

In particular, the minimum and the maximum, $(X_{[1]}, X_{[n]})$, have the joint density

$$g_{1,n;n}(x,y) = n(n-1)[F(y)-F(x)]^{n-2} f(x)f(y).$$

From the joint distribution of two order statistics we can find the distribution of various other statistics, e.g., the sample range $R = X_{[n]} - X_{[1]}$. The pdf and cdf of the sample range R are, respectively,

$$g_R(R) = n(n-1) \int_{-\infty}^{\infty} \left[\frac{F(x+R)}{-F(x)} \right]^{n-2} f(x)f(x+R)dx$$

and

$$G_R(R) = n \int_{-\infty}^{\infty} \left[\frac{F(x+R)}{-F(x)} \right]^{n-1} f(x)dx.$$

The range statistics allow us to develop procedure to test the hypothesis of equivalence of means. Furthermore, the joint pdf of any number of the order statistics can be constructed, in particular, the joint pdf of all of the order statistics is

$$g_{1,2,\dots,n;n}(X_{[1]}, X_{[2]}, \dots, X_{[n]}) = n! f(X_{[1]})f(X_{[2]}) \dots f(X_{[n]}).$$

In the case that f is the uniform $[0,1]$ distribution,

$$g_{u,v;n}(x,y) = n! \frac{x^{u-1} [1-y]^{n-v} [y-x]^{v-u-1}}{(u-1)! (n-v)! (v-u-1)!}$$

and

$$\text{Cov}[X_{[u]}, X_{[v]}] = \frac{u(n-v+1)}{(n+1)^2(n+2)}.$$

As expected, $\text{Cov}[X_{[u]}, X_{[v]}]$ decreases as the difference between $v-u$ increases, given u or v . Moreover, $\text{Cov}[X_{[1]}, X_{[n]}] \rightarrow 0$, as $n \rightarrow \infty$. That is, in large samples the minimum and the maximum are in general approximately independent. Furthermore, the pdf and cdf of the sample range, respectively, are

$$g_R(R) = n(n-1)R^{n-2} \int_0^{1-R} dx = n(n-1)R^{n-2}(1-R) = \beta(R; n-1, 2),$$

and

$$G_R(R) = n(1-R)R^{n-1} + R^n.$$

From this we can deduce that

$$E[R] = \frac{n-1}{n+1}$$

and

$$\text{Var}[R] = \frac{2(n-1)}{(n+1)^2(n+2)}.$$

That is, the sample range R approaches the true range and variance of the sample range R becomes smaller as the sample size n becomes larger.

For $1 \leq u < v \leq n$, the conditional distribution of $X_{[v]}$ given $X_{[u]} = x_a$ is the same as the unconditional distribution of the $(v - u)^{\text{th}}$ order statistic in a sample of size $n - u$ from a new distribution, namely the original F truncated at the left at x_a . In notation,

$$\begin{aligned} g_{X_{[v]}|X_{[u]}=x_a}(x) &= \frac{(n-u)!}{(v-u-1)!(n-v)!} \left[\frac{F(x) - F(x_a)}{1 - F(x_a)} \right]^{v-u-1} \\ &\quad \left[\frac{1 - F(x)}{1 - F(x_a)} \right]^{n-v} \frac{f(x)}{1 - F(x_a)}, x > x_a. \end{aligned}$$

Similarly, for $1 \leq u < v \leq n$, the conditional distribution of $X_{[u]}$ given $X_{[v]} = x_b$ is the same as the unconditional distribution of the u^{th} order statistic in a sample of size $v - 1$ from a new distribution, namely the original F truncated at the right at x_b . In notation,

$$\begin{aligned} g_{X_{[u]}|X_{[v]}=x_b}(x) &= \frac{(v-1)!}{(u-1)!(v-1-u)!} \left[\frac{F(x)}{F(x_b)} \right]^{u-1} \\ &\quad \left[1 - \frac{F(x)}{F(x_b)} \right]^{v-1-u} \frac{f(x)}{F(x_b)}, x < x_b. \end{aligned}$$

For more information of conditional distribution of order statistics, see (DasGupta, 2011). These formula can be used to estimate the distribution of sample range R ; without storing and sorting the entire sequence.

Order Statistics from Correlated Normal Random Variables

Let $\Phi(x)$ and $\phi(x)$ be, respectively, the cdf and the pdf of a standardized normal random variable. In the case that $\{X_i\}$ for $i = 1, 2, \dots, n$, are standardized normal random variables with correlation matrix $\{\rho_{ij} = \rho \geq 0, \text{ for } i \neq j\}$, it can be shown (Gupta et al., 1973) that

$$\begin{aligned} F_u(h; \rho) &= \Pr[X_{[u]} \leq h] \\ &= \int_{-\infty}^{\infty} I_{q(x)}(u, n - u + 1) d\phi(x), \end{aligned}$$

where $q(x) = \Phi\left(\frac{x\sqrt{\rho} + h}{\sqrt{1 - \rho}}\right)$, and

$I_{q(x)}(a, b)$ ($a, b > 0$) is the usual incomplete beta function. When $u = n$ the equation is reduced to

$$\begin{aligned} F_n(h; \rho) &= \Pr[X_{[n]} \leq h] \\ &= \int_{-\infty}^{\infty} \Phi^n\left(\frac{x\sqrt{\rho} + h}{\sqrt{1 - \rho}}\right) \phi(x) dx. \end{aligned}$$

By the symmetry of the normal distribution, $\Pr[X_{[1]} \geq -h]$ is also equal to $F_n(h; \rho)$. When the correlation matrix has the structure $\rho_{ij} = c_i c_j$ ($i \neq j$), where $-1 \leq c_i \leq 1$ for $i = 1, 2, \dots, n$, then X_i can be represented as

$$X_i = c_i Z_0 + \sqrt{1 - c_i^2} Z_i, \text{ for } i = 1, 2, \dots, n,$$

where $Z_i, i = 0, 1, \dots, n$, are independent standard normal random variables. If $\rho_{ij} = \rho \geq 0$, then

the structural assumption that $\rho_{ij} = c_i c_j$ is satisfied by taking $c_i = \sqrt{\rho}$ for all i .

Normal distributions' pdf cannot be integrated in closed form, and hence tables of the cdf or computer programs are necessary to compute probabilities and quantiles for normal distributions. The complexity increases when variables are correlated. Gupta et al. (1973) point out that in several cases of applications, e.g., ranking and selection, the percentage points (quantile) of the distribution of $X_{[n]}$ are needed and provide tables of percentage points for several selected values of n and positive ρ . See Chen (2014) for more information.

Empirical Distribution Functions

In many cases, we want to use the observed data themselves to specify a distribution, called an empirical distribution, to approximate the true distribution. Consider an iid sequence $\{X_i\}$ for $i = 1, 2, \dots, n$, with distribution function F . One of the simplest and most important functions of order statistics is the sample cumulative distribution function F_n , which can be constructed by placing a mass $1/n$ at each observation X_i . Hence, F_n may be represented as

$$F_n(x) = \frac{1}{n} \sum_{i=1}^n I(X_i \leq x), -\infty < x < \infty.$$

Here $I(\cdot)$ is the indicator function. That is, the empirical cdf $F_n(x)$ for all real x , represents the proportion of sample values that do not exceed x . Namely,

$$F_n(x) = 0, x < x_{[1]},$$

$$F_n(x) = \frac{i}{n}, x_{[i]} \leq x < x_{[i+1]},$$

$$F_n(x) = 1, x_{[n]} \leq x.$$

For each fixed x , the strong law of large number implies that $F_n(x) \rightarrow F(x)$ asymptotically. Hence, we can get a good idea of what the true F is by studying F_n . Furthermore, natural estimators (obtained via empirical cdf) of estimating any characteristic properties of the distribution are appropriate and perform well.

In many cases, we are interested whether samples are drawn from the same distributions. It is very important in simulation to ensure that distributions of input parameters represent the underlying distributions correctly. The Q-Q (Quantile-Quantile) plot is a graphical evaluation of goodness of fit, it is the graphical representation of the points $(F^{-1}(p), x_{[np]})$, where population quantiles are recorded along the horizontal axis and the sample quantiles on the vertical axis. If the samples are in fact from F , we expect the Q-Q plot to be close to a straight line. If not, the plot may show nonlinearity at the upper or lower ends, which may be an indication of the presents of outliers. If the nonlinearity shows up at other points as well, one could question the validity of the assumption that the parent cdf is F . On the other hand, a goodness-of-fit test is a statistical hypothesis test that is used to assess formally whether the observations $X_1, X_2, \dots, X_n$ are independent samples from a particular distribution with distribution function F . The goodness-of-fit tests include Chi-square test, Kolmogorov-Smirnov test, and Anderson-Darling test (Law, 2014).

Furthermore, the density function $f = F'$. Hence, we can use the derivative of F_n to estimate f . We consider the central finite difference

$$f_n(x) = \frac{F_n(x+w) - F_n(x-w)}{2w}.$$

Here $2w$ is the width of bins (or intervals), which are disjointed categories. A graphical representation of $f_n(x)$ is called a histogram. See (Silverman, 1986) for more information on density estimation.

Test of Independence

The usual method of confidence interval construction from classical statistics, which assumes iid observations, is not directly applicable in many simulation procedures because simulation output data are generally correlated. Hence, it is important to determine whether the output data appear to be independent before applying random sampling theory. If the output data sequence appears to be dependent, special techniques need to be used to mitigate the effect of dependence, e.g., constructing confidence interval with batch means (Law, 2014). In dealing with this problem various tests of independence based on order statistics have been proposed, e.g., the runs-up and runs-down tests (Knuth, 1997). Briefly, a run up (run down) is a monotonically increasing (decreasing) subsequence. The tests compare the proportion of different run lengths to what would be expected under the independent null hypothesis in order to check whether the sequence appears to be independent.

The runs tests of independence require the underlying distributions of the random variables to be continuous. To adapt for discrete random variables, we will increase the run length with probability $1/(\tau+1)$ when two successive observations are equal, where τ is the current run length. Note that if there are $\tau+1$ observations, the possibility of the $(\tau+1)^{\text{th}}$ observation being the largest is $1/(\tau+1)$. If the distribution is continuous, the probability of a subsequence having run length τ is $\tau/(\tau+1)!$, under the null hypothesis that the sequence consists of iid random variables. We then use the Chi-square test on the observed frequency of each run length to

determine whether the sequence appears to be independent.

Lag l observations of sequence $X_i, i = 1, 2, \dots, n$, refers to the sequence $X_{(i-1)l+1}, i = 1, 2, \dots, n/l$. For example, lag 2 observations is the sequence $X_1, X_3, \dots, X_{(n/2-1)2+1}$.

Chen & Kelton (2010) use tests of independence to determine simulation run length. The procedure determines the lag l so that observations that at least $l-1$ observations apart will be essentially independent. The required simulation run length is then determined based on l . For example, if the required sample size for an iid sequence is n , then the required sample size for a correlated sequence is nl .

Indifference-Zone Selection

Discrete-event simulation has been widely used to compare alternative system designs or operating policies. When evaluating k alternative system designs, we select one or more system as the best and control the probability that the selected systems really are the best. Let CS denote the event of "correct selection." In a stochastic simulation, a CS can never be guaranteed with certainty. The probability of CS, denoted by $P(\text{CS})$, is a random variable depending on sample sizes and other uncontrollable factors. Moreover, in practice, if the difference between μ_{i_1} and μ_{i_2} is very small, we might not care if we mistakenly choose system i_2 , whose expected response is μ_{i_2} . The practically significant difference d^* , (a positive real number) between a desired and a satisfied system is called the indifference zone in statistical literature, and it represents the smallest difference which we care about. Therefore, we want a procedure that avoids making a large number of replications or batches to resolve differences less than d^* . That means we want $P(\text{CS}) \geq P^*$ provided that $\mu_{i_2} - \mu_{i_1} \geq d^*$, where the minimal CS probabil-

ity P^* and the “indifference” amount d^* are both specified by the users.

The indifference-zone selection procedure of Dudewicz and Dalal (1975) to select the best of k systems proceeds as follows.

1. Simulate the initial samples for all systems.
Compute the first-stage sample means with the equation and the sample variances with the equation

$$S_i^2(n_0) = \frac{1}{n_0 - 1} \sum_{j=1}^{n_0} \left(X_{ij} - \bar{X}_i^{(1)}(n_0) \right)^2$$

for $i = 1, 2, \dots, k$.

2. Compute the required sample sizes with the equation

$$N_i = \max \left(n_0 + 1, \left(h_1 S_i(n_0) / d^* \right)^2 \right), \text{ for } i = 1, 2, \dots, k.$$

Here h_1 (a positive real number that depends on k , P^* , and n_0) is a critical constant that will be described later.

3. Simulate additional $N_i - n_0$ samples, for $i = 1, 2, \dots, k$.
4. Compute the second-stage sample means with the equation

$$\bar{X}_i^{(2)}(N_i - n_0) = \frac{1}{N_i - n_0} \sum_{j=n_0+1}^{N_i} X_{ij},$$

for $i = 1, 2, \dots, k$.

5. Compute the weighted sample means with the equation

$$\widetilde{X}_i(N_i) = W_{i1} \bar{X}_i^{(1)}(n_0) + W_{i2} \bar{X}_i^{(2)}(N_i - n_0),$$

for $i = 1, 2, \dots, k$

and select the system with the smallest $\widetilde{X}_i(N_i)$.
The weights can be derived from the equations

$$W_{i1} = \frac{n_0}{N_i} \left[1 + \sqrt{1 - \frac{N_i}{n_0} \left(1 - \frac{(N_i - N_0)(d^*)^2}{h_1^2 S_i^2(n_0)} \right)} \right]$$

and $W_{i2} = 1 - W_{i1}$, for $i = 1, 2, \dots, k$. The expression for W_{i1} was chosen to guarantee that the variable $\left(\widetilde{X}_i(N_i) - \mu_i \right) / (d^* / h_1)$ would have a t distribution with $n_0 - 1$ df; see Dudewicz and Dalal (1975).

Let T_i for $i = 1, 2, \dots, k$, be independent t -distributed random variables with $n_0 - 1$ df and let F denote the cdf of the t distribution with $n_0 - 1$ df. Let $\tilde{X}_{c_u} = \min_{2 \leq i \leq k} \tilde{X}_{i1}$, under the null hypothesis that $\mu_{i1} + d^* = \mu_{i2} = \dots = \mu_{ik}$, we can write

$$\begin{aligned} P(CS) &= P \left[\tilde{X}_{i1} < \tilde{X}_{c_u} \right] \\ &= P \left[\frac{\tilde{X}_{i1} - \mu_{i1}}{d^* / h_1} < \frac{\tilde{X}_{c_u} - \mu_{c_u}}{d^* / h_1} + \frac{\mu_{c_u} - \mu_{i1}}{d^* / h_1} \right] \\ &= P \left[T_{i1} < T_{c_u} + h_1 \right] \\ &= \int_{-\infty}^{\infty} F(t + h_1) g_{1:k-1}(t) dt. \end{aligned}$$

We equate the right-hand side to P^* and solve for the critical constant h_1 . Note that T_{c_u} is the first order statistic of $k - 1$ random variate T .

Generalized Subset Selection

Mahamunulu (1967) considers a generalized version of the selection problem. The goal is to select a subset of size m contains at least c of the v best of k systems, where $\max(I, m + v + I - k) \leq c \leq \min(m, v)$ and $\max(m, v) \leq k - 1$. If $m = v = 1$,

then the problem is to choose the best system. When $m > v = 1$, we are interested in choosing a subset of size m contains the best. If $m = v > 1$, we are interested in choosing the m best systems. We now assess the P(CS) of this subset selection problem. The LFC (Least Favorable Configuration) of this problem is $\mu_{i_1} = \mu_{i_2} = \dots = \mu_{i_v}$ and $\mu_{i_v} + d^* = \mu_{i_{v+1}} = \dots = \mu_{i_k}$. Indifference-zone selection procedures determine the number of additional replications based on the LFC because the minimal P(CS) occurs in this setting. We derive the P(CS) of subset selection with order statistics. Let $\tilde{X}_c$ be the c^{th} smallest weighted sample mean from system i_l for $l = 1, 2, \dots, v$ and let μ_c be its unknown true mean. Let $\tilde{X}_u$ ($u = m - c + 1$) be the smallest weighted sample mean from system i_l for $l = v + 1, v + 2, \dots, k$ and let μ_u be its unknown true mean. Then correct selection occurs if and only if $\tilde{X}_c < \tilde{X}_u$. We would like to point out that systems c and u are unknown. However, $\tilde{X}_c \sim g_{c:v}(t)$ and $\tilde{X}_u \sim g_{u:k-v}(t)$. The P(CS) of subset selection can be written as

$$\begin{aligned} P(CS) &= P\left[\tilde{X}_c < \tilde{X}_u\right] \\ &= P\left[T_c < T_u + \frac{\mu_u - \mu_c}{d^* / h}\right] \\ &\geq P\left[T_c < T_u + h\right]. \end{aligned}$$

Here h is a critical constant. The inequality follows because $\mu_u - \mu_c \geq \mu_{i_{v+1}} - \mu_{i_v} \geq d^*$. Furthermore, if $d_{cu} = \mu_u - \mu_c$ is used instead of d^* in the above equations, then we obtain strict equality. For more information on subset selection, see (Chen, 2009). Note that the value h is determined such that $P\left[T_c < T_u + h\right] = P^*$. Let $\gamma = T_c - T_u$ then $P\left[\gamma < h\right] = P^*$. That is, under the LFC the value of the critical constant h is the P^* quantile of the distribution of γ . We can use this property to estimate the value of h for the problem at hand.

Hypothesis Tests of Equivalence of Means

This section investigates performing the hypothesis testing of equivalence of mean of multiple systems. The most useful comparison of the system means is done by comparing each system with the unknown best system or best systems within the group. Consider sample means of certain observations drawn at random from k systems. The sample mean of system i with N_i samples

$$\bar{X}_i = \frac{1}{N_i} \sum_{j=1}^{N_i} X_{ij}.$$

Let $\bar{X}_j$, $j = 1, 2, \dots, k$ be another set of sample means that are independent of $\bar{X}_i$ and let

$$\bar{X}_o = \frac{1}{k} \sum_{j=1}^k \bar{X}_j \text{ and } S^2 = \frac{1}{k-1} \sum_{j=1}^k (\bar{X}_j - \bar{X}_o)^2.$$

The range of sample means $W = \bar{X}_{[k]} - \bar{X}_{[1]}$ and the ratio, $q = W/S$, of the sample range to an independent root-mean-square estimate, S , of the population standard deviation, σ , is called a studentized range. Tukey's range test to find which means are significantly different from one another is based on the distribution of q (Snedecor and Cochran, 1989). Note that Tukey's range test assumes equal variances and uses equal sample sizes for each system.

Chen (2011) considers the equivalence test with critical region $R = \left\{ \bar{X}_{[k]} - \bar{X}_{[1]} \leq \delta \right\}$, where $\delta > 0$ is a user-specified upper bound of the sample range for the hypothesis test. Note that in our cases variances may be unequal among systems and the studentized range can no longer be computed in a straightforward manner.

Let $\tilde{X}_i$ (i.e., $\tilde{X}_i(N_i)$) be the weighted sample means and let

$$T_i = \frac{\tilde{X}_i - \mu_i}{\delta / h_3}.$$

Here h_3 is a critical constant. Note that the weight needs to be computed with d replaced by δ and the required sample sizes N_i need to be computed by equation (1), which will be described later. Moreover, T_i 's are independent t -distributed random variables with $n_0 - 1$ degrees of freedom (df). Let F denote the cdf of the t distribution with $n_0 - 1$ df. Let μ_{i_l} be the l^{th} smallest of the μ_i 's, so that $\mu_{i_1} \leq \mu_{i_2} \leq \dots \leq \mu_{i_k}$ and let $\tilde{X}_{c_l}$ denote the l^{th} smallest weighted sample mean such that $\tilde{X}_{c_1} \leq \tilde{X}_{c_2} \leq \dots \leq \tilde{X}_{c_k}$. Under the null hypothesis that $\mu_{i_1} = \mu_{i_2} = \dots = \mu_{i_k}$, we can write the probability of correct decision

$$\begin{aligned} P(\text{CD}) &= P\left[\tilde{X}_{c_k} - \tilde{X}_{c_1} \leq \delta\right] \\ &= P\left[\frac{\tilde{X}_{c_k} - \mu_{c_k}}{\delta / h_3} - \frac{\tilde{X}_{c_1} - \mu_{c_1}}{\delta / h_3} \leq \frac{\delta}{\delta / h_3}\right] \\ &= P\left[T_{c_k} - T_{c_1} \leq h_3\right] \\ &= G_R(h_3). \end{aligned}$$

We then equate the right hand side to P^* and solve for h_3 . Numerical approximation has been used to solve the integration. Nevertheless, other approach can be used to solve h_3 , which will be discussed later.

The steps of testing the null hypothesis that all means are equal are as follows.

1. Simulate the initial samples for all systems. Compute the first-stage sample means with the equation and the sample variances with the equation

$$S_i^2(n_0) = \frac{1}{n_0 - 1} \sum_{j=1}^{n_0} \left(X_{ij} - \bar{X}_i^{(1)}(n_0)\right)^2$$

for $i = 1, 2, \dots, k$.

2. Compute the required sample sizes with the formula

$$N_i = \max\left\{n_0 + 1, \left(h_3 S_i(n_0) / \delta\right)^2\right\}, \text{ for } i = 1, 2, \dots, k. \quad (1)$$

3. Simulate additional $N_i - n_0$ samples.
4. Compute the second-stage sample means with the formula

$$\bar{X}_i^{(2)}(N_i - n_0) = \frac{1}{N_i - n_0} \sum_{j=n_0+1}^{N_i} X_{ij}, \text{ for } i = 1, 2, \dots, k.$$

5. Compute the weighted sample means $\tilde{X}_i$ for $i = 1, 2, \dots, k$. Reject the null hypothesis when

$$\tilde{X}_{c_k} - \tilde{X}_{c_1} > \delta;$$

otherwise do not reject the null hypothesis.

Estimating the Critical Constant

In this section, we present an approach to estimate the critical constant for selection procedures. Let variables T_{i_l} for $l = 1, 2, \dots, k$ be independently and identically t -distributed with $n_0 - 1$ df. The selection procedure of Dudewicz and Dalal (1975) is derived from the equation

$$\begin{aligned} P(CS) &\geq P\left[T_{i_1} < T_{i_l} + h_1, l = 2, 3, \dots, k\right] \\ &= \int_{-\infty}^{\infty} F^{k-1}(t + h_1) f(t) dt, \end{aligned}$$

where f and F are the pdf and cdf of the t distribution with $n_0 - 1$ df, respectively. The equality holds exactly under the LFC. We equal the right-

hand side to P to solve for h_1 . Recall that $T_{c_u} = \min_{2 \leq l \leq k} T_{i_l}$, hence, $P[T_{i_1} - T_{c_u} < h_1] = P^*$. That is, the critical constant h_1 is the P^* quantile of the variable $T_{i_1} - T_{c_u}$. Similarly, h_3 is the P^* quantile of the variable $T_{c_k} - T_{c_1}$ and h is the P^* quantile of the variable $T_c - T_u$.

Chen & Kelton (2008) develop a quantile-estimation procedure that controls the precision of quantile estimates by ensuring that the p quantile estimator $\hat{x}_p$ satisfies the following:

$$P[x_p \in \hat{x}_{p \pm \varepsilon}] \geq 1 - 2\alpha_1,$$

or equivalently $P[|F(\hat{x}_p) - p| \leq \varepsilon] \geq 1 - 2\alpha_1.$ (2)

Using this precision requirement (i.e., (2)), the required sample size np for a fixed-sample-size procedure of estimating the p quantile of an iid sequence is the minimum np that satisfies

$$np \geq \frac{z_{1-\alpha_1}^2 p(1-p)}{\varepsilon^2},$$

where $z_{1-\alpha_1}$ is the $1 - \alpha_1$ quantile of the standard normal distribution, ε is the maximum proportional half-width of the confidence interval, and $1 - 2\alpha_1$ is the confidence level. For example, if the data are independent and one wants to have 95% confidence that the coverage of the 0.9 quantile estimator has no more than $\varepsilon = 0.0001$ deviation from the true but unknown quantile, the required sample size is $np \geq 34574400$ (i.e., $1.960^2 0.9(1 - 0.9)/0.0001^2$). Consequently, we will have 97.5% confidence that the quantile estimate will cover at least $p - 0.0001$ (for $p \geq 0.9$), with sample size 34574400.

Quantile estimates obtained through order statistics directly (i.e., sample quantiles) required storing and sorting the entire sequence, which is computationally intensive. To avoid storing and sorting the entire sequence, a modified version of

the histogram- approximation procedure of Chen & Kelton (2008) was used to estimate quantiles.

FUTURE TRENDS

Order statistics continue to be key components of any data analysis. Algorithms developed based on order statistics will be incorporated into many statistical packages and will be readily available for practitioners.

CONCLUSION

Order statistics have proved useful for both theoretical and computational purposes. Important special cases of order statistics are the minimum and maximum value of samples, and the sample median and other sample quantiles. We have investigated several properties of order statistics and discussed how order statistics are applied in statistical analysis, e.g., generate the distributions of order statistics without sorting, build empirical distributions, and validate empirical distributions with goodness-of-fit tests. We also presented several procedures that are derived based on the inference of order statistics, e.g., hypothesis tests of equivalence of means, ranking and selection, and quantile estimation. Properties of order statistics allow us to derive many algorithms in a concise manner. These procedures are easy to understand and simple to implement.

KEY TERMS AND DEFINITIONS

Critical Constant: In ranking and selection, the critical constant is a required parameter for computing the required sample sizes and is the P^* quantile of the difference of two specific random values.

Empirical Distribution Function: The cumulative distribution function (cdf) associated with the empirical observations of the sample. The empirical distribution function estimates the true underlying cdf of the sample.

Histogram: A graphical representation showing the distribution of data.

Indifference Zone: We don't distinguish values that are deviated less than a significant amount (the indifference amount), i.e., they are within in the indifference zone.

Order Statistics: The collection of sample observations sorted in ascending order.

Q-Q Plot: A probability plot for comparing two probability distributions by plotting their quantiles against each other.

Quantile Function (Inverse Distribution Function): The quantile function (given a probability p) returns the value at or below which $100p$ percent of the population lies.

Range Statistics: The statistics of the difference between the maximum and minimum observations. Range statistics give an estimate of the spread of the data.

Tests of Independence: Statistical null hypothesis tests to determine whether sequences of observations appear to be independent.

Recommender Technologies and Emerging Applications

D**Young Park**

Bradley University, USA

INTRODUCTION

A *recommender system* (or *recommendation system*) is a software application that provides users with personalized recommendations of goods, services or other potentially relevant and interesting information, and thus helps users find useful items in the information overload (Aggarwal, 2016; Resnick & Varian, 1997; Ricci, Rokach, & Shapira, 2015). The field of recommender systems is highly interdisciplinary and based on various technologies. Though relatively new, recommender technologies have made significant progress for the last decade.

A variety of recommender systems have been developed and used mainly in e-commerce application domains, including Amazon.com, BarnesandNoble.com, Netflix.com, mystrands.com, and Yahoo.com (Konstan et al., 1997; Sarwar, Karypis, Konstan, & Riedl, 2000; Schafer, Konstan, & Riedl, 2001). Over the last decade, recommender systems have proven very useful in increasing sales and retaining consumers, and are considered an effective personalization tool in the e-commerce environment (Adomavicius & Tuzhilin, 2005; Goy, Ardissono, & Petrone, 2007; Jannach, Zanker, Felfernig, & Friedrich, 2011; Ricci et al., 2015; Sarwar et al., 2000; Schafer et al., 2001;). One illustration is the famous Netflix competition (2006-2009), which offered a one million dollar prize in exchange for an algorithm to enhance the recommendation accuracy (i.e., movie rating prediction) of its recommender systems (Bell, Koren, & Volinsky, 2010).

This chapter presents an overview of the field of recommender technologies and their emerging

application domains. We characterize current major recommender system approaches in a unifying model and describe emerging applications of recommender technologies beyond traditional e-commerce. We conclude with emerging and future trends and topics, as well as additional readings in the area of recommender technologies and applications.

BACKGROUND

Since the first major recommender systems emerged in the mid-1990s (Resnick & Varian, 1997), a large number of recommender systems have been developed and used in a wide range of e-commerce environments and improved by continuing research.

A typical recommender system provides users with *personalized* recommendations of items such as goods, services or information to guide users to find items that are relevant to them. Recommendations are based on past and present profiles of users with respect to items. The *personalized recommendation problem* can be described as follows:

Given a target user, produce personalized recommendations of items relevant to the target user.

To solve this recommendation problem, a recommender system generally uses three types of data—data about the users (*U_data*), data about the items such as goods, services or information (*I_data*), and data about the relevance (such as rating, evaluation, purchase, or interest) relation between the users and the items (*R_data*):

Figure 1. A model for recommender systems

- U_data contains a set of all users and some optional additional information about all users.
- I_data contains a set of all items and some optional additional information about all items.
- R_data contains relevance information (such as rating, evaluation, purchase, or interest) of the item to the user. Such information can be viewed and represented as a partial function (or matrix) that maps a pair of user and item into a relevance value.

As shown in Figure 1, a recommender system can be modeled as follows:

Given a target user, a recommender system recommends a list of new items that are most relevant to the target user by using U_data , I_data , and R_data .

The user data is constructed for all existing users and the item data is constructed for all existing items. The user-item relevance data is constructed over time and can be obtained either explicitly from user participation (*explicit relevance feedback*), inferred implicitly from user behavior (*implicit relevance feedback*), or both.

In order to find items that are relevant to the target user, recommender systems are premised on the *similarity* between users or between items. A number of similarity metrics are used to represent the degree of similarity between users or items. *Pearson Correlation* and *Cosine Similarity* are among most widely used metrics in recommender systems.

The recommendation process typically consists of two phases – the prediction phase and the suggestion phase. First, the recommended list of most relevant and new items for the target user is determined by predicting the unknown relevance values of new items by the target user. The predicted relevance value of a new item is estimated from the relevance values of the item from some of the most similar users (i.e., nearest user neighbors) or the relevance values of some of the most similar items (i.e., nearest item neighbors) using some prediction algorithm such as the weighted sum. Second, the recommender system typically recommends a list of top n items with the highest predicted relevance values.

The quality of recommender systems is evaluated in many ways (Herlocker, Konstan, Terveen, & Riedl, 2004). The accuracy of the recommended items is the most frequently evaluated measure. Popular accuracy metrics include *mean absolute error* (MAE, or the average of absolute differences

between real feedback values and predicted feedback values), *mean square error* (MSE), *root mean squared error* (RMSE), *precision* (the number of relevant items recommended divided by the total number of recommended items), and *recall* (the number of relevant items recommended divided by the total number of existing relevant items).

MAJOR RECOMMENDER TECHNOLOGIES

Various recommendation technologies have been used to develop more effective and efficient recommender systems in a range of application domains (Adomavicius & Tuzhilin, 2005). Each approach has strengths and weaknesses. Major recommender system approaches can be classified as follows: *content-based recommender*, *collaborative recommender* and *hybrid recommender*. Other approaches include knowledge-based recommender and demographic recommender.

The major recommender approaches (Figure 2) can be characterized within a single unifying model (Figure 1). Each approach uses three kinds of data — U_data , I_data and R_data . However, each approach differs in

- The information contained in the data, and
- How the three kinds of data are used to produce the most relevant items for a given target user.

Content-Based Recommender

The content-based recommendation approach, which is based on the *content* of items, underlies a number of recommender systems (Pazzani & Billsus, 2007; Lops, Gemmis, & Semeraro, 2011). This system basically recommends a list of items with similar content to the items that were given good relevance feedback by the target user. The pure content-based recommender system uses

- U_data = A set of all users.
- I_data = A set of all items and a partial function that maps an item-feature pair (i.e., item, feature) into a content description value. (This function contains information about items and features describing the content of the items.)
- R_data = A partial function that maps a user-item pair into a relevance value.

Similarity between items with respect to content description features can be measured using various similarity metrics. Given a target user, the recommendation process of the content-based approach has three main steps:

- Step 1:** Find items for which the target user provided good relevance feedback using R_data .
- Step 2:** Select items with content similar to that of the items found in Step 1 using I_data .
- Step 3:** Recommend a list of items from the items selected in Step 2 that are most relevant and new to the target user.

Figure 2. Major recommender approaches

Limitations of Content-Based Recommender

The effectiveness of content-based recommender systems depends on how well the items are described by features, and thus is often limited. These systems tend to recommend items that are similar to those already recommended (called *the item overspecialization problem*), and cannot recommend items for new users until they provide enough relevance feedback (called *the new user problem*). However, content-based recommender systems can recommend new items.

Collaborative Recommender

The collaborative recommendation approach recommends items through *user collaborations*. Numerous recommender systems using the collaborative recommendation approach have been proposed, and this approach is the most widely used and proven method of providing recommendations (Herlocker et al., 2004; Schafer, Frankowski, Herlocker, & Sen, 2007). There are two types of *neighborhood-based* collaborative recommender systems (Sarwar, Karypis, Konstan, & Riedl, 2001; Linden, Smith, & York, 2003):

- *User-to-user collaborative recommender*
- *Item-to-item collaborative recommender*

User-to-User Collaborative Recommender

The user-to-user collaborative filtering approach is based on user-to-user similarity. It recommends a list of items given relevance feedback by other users similar to that provided by the target user. The user-to-user collaborative recommender system uses

- U_data = A set of all users.
- I_data = A set of all items.
- R_data = A partial function that maps a user-item pair into a relevance feedback value.

Similarity between two users is based on relevance feedback for all items provided by both users. Different similarity metrics can be used to describe user similarity. Given a target user, the recommendation process of the user-to-user collaborative recommender system has three main steps:

- Step 1:** Find consumers who are similar to the target consumer using R_data .
- Step 2:** Select items given good feedback by the similar consumers found in Step 1 using R_data .
- Step 3:** Recommend a list of items from the items selected in Step 2 that are most relevant and new to the target user.

Item-to-Item Collaborative Recommender

The item-to-item collaborative filtering approach is based on item-to-item similarity. It recommends a list of items that are similar to the items that were given good relevance feedback by the target user. The item-to-item collaborative recommender system uses

- U_data = A set of all users.
- I_data = A set of all items & a partial function that maps an item-item pair (i.e., item and item) into a similarity value. (This function contains information about similarity between items.)
- R_data = A partial function that maps a user-item pair into a relevance feedback value.

Similarity between two items is based on relevance feedback received from all users concerning both items. Note, however, that the content-based approach uses similarity between items with respect to content description features. The similarity between items with respect to users is measured using different similarity metrics. The partial function that maps an item-item pair to a similarity value can be constructed using

R_data in the offline stage in advance. Given a target user, the recommendation process of the item-to-item collaborative recommender system has three main steps.

Step 1: Find items given good feedback by the target user using R_data .

Step 2: Select items that are similar to the items found in Step 1 using I_data .

Step 3: Recommend a list of items from the items selected in Step 2 that are most relevant and new to the target user.

Comparison of Collaborative Recommender Approaches

While user-to-user collaborative filtering is based on similarity between users, item-to-item collaborative filtering is based on similarity between items. Item-to-item collaborative filtering is more algorithmically efficient and has shown better recommendation accuracy than user-to-user collaborative filtering.

Item-to-item collaborative filtering is an example of the *model-based* method. The model-based method builds a model of the user-item relevance feedback data offline then uses the model to generate items for recommendation. Amazon's product recommender system is an item-to-item collaborative recommender (Sarwar et al., 2001). In contrast, user-to-user collaborative filtering and the content-based method are examples of the *memory-based* method. The memory-based method memorizes and then uses the entire user-item relevance feedback data to find items for recommendation. The model-based method shows better scalability than the memory-based method..

Latent Factor Model-Based Collaborative Recommender

The latent factor model-based collaborative filtering approach is a model-based approach based on

the concept of matrix factorization (decomposition) of relevancy feedback data (R_data). This approach tends to show high recommendation accuracy in various applications, and a number of matrix factorization techniques are widely used in collaborative recommenders (Koren, Bell, & Volinsky, 2009). Models based on matrix factorization were used in the movie recommendation algorithm by the team who won the Netflix prize, BellKor's Pragmatic Chaos.

Limitations of Collaborative Recommender

The recommendation quality of collaborative filtering-based approaches depends on user feedback on items. But the available feedback is usually smaller compared with all possible feedback (called *the relevance feedback sparsity problem*). Collaborative filtering-based approaches also suffer from the new user problem and cannot recommend new items until they have enough feedback from users (called *the new item problem*).

Hybrid Recommender

In order to overcome the limitations of each approach and improve accuracy through synergy, the hybrid recommendation approach recommends items by combining two or more approaches, including the two major approaches (content-based and collaborative filtering-based) and the knowledge-based approach (Burke, 2007). Netflix's movie recommender system is a hybrid recommender that combines the content-based approach and the collaborative approach.

The combination (hybridization) can be done in many different ways - monolithic hybridization, parallel hybridization and pipelined hybridization. Many recommender systems adopt the hybrid approach and tend to result in better recommendations.

TRADITIONAL E-COMMERCE RECOMMENDER APPLICATIONS

With the explosive growth goods, services and information available on the Web under the e-commerce umbrella (in either commercial or non-commercial contexts), it has become increasingly difficult for consumers to find what they are searching for in a timely manner. By providing consumers with personalized recommendations, recommender systems can help consumers find relevant and interesting products in the age of information overload.

The traditional application domain of recommender technologies is e-commerce (Schafer et al., 2001; Lu, Wu, Mao, Wang, & Zhang, 2015; Ricci et al., 2015). In the e-commerce environment, the users are consumers and the recommendable items are products including a wide variety of goods, services or information. E-commerce recommender systems provide consumers with personalized recommendations of relevant products, including movies, videos, news, songs, books, images, blogs, games, restaurants, television programs, people, documents, jokes, places, hotels, travel destinations, accommodations, real estates, websites, and tags.

Personalized recommendations can be viewed as part of the personalization activity of e-commerce applications. Recommender technologies have become and will continue to be an important tool for e-commerce personalization.

EMERGING RECOMMENDER APPLICATIONS

Personalized recommender technologies have increasingly been applied to various other domains beyond e-commerce. Notable emerging application domains, discussed below, include

- **Education:** Learning, teaching and advising.

- **Engineering:** Software engineering, requirements engineering and data/knowledge engineering.

Recommender Applications in Education

One notable emerging application domain is that of education, namely, learning (including e-learning), teaching and academic advising. In the educational context, the users are students, teachers or academic advisors, and the recommendable items are products such as educational goods, services or information. Educational recommender systems can guide students, teachers or advisors by suggesting personalized recommendations of relevant educational goods, services or information during the learning, teaching or academic advising process.

A significant number of educational recommender systems, involving courses, learning materials, topics and grades, have been proposed and deployed in this application domain (Manouselis, Drachsler, Verbert, & Duval, 2013; Manouselis, Drachsler, Verbert, & Santos, 2014).

Recommender Applications in Engineering

Another notable emerging application domain is the technical domain of engineering, including software engineering, requirements engineering and data/knowledge engineering. Engineering processes involve many complex and knowledge-intensive activities. In the technical engineering environment, the users are engineers and the recommendable items are products such as engineering goods, services or information. Engineering recommender systems can assist engineers with personalized recommendations of relevant engineering goods, services or information during the complex engineering process.

Various software engineering recommender systems have been presented for products such as process, codes, issue reports, tools, commands and

operations (Robillard, Walker, & Zimmermann, 2010; Robillard, Maalej, Walker, & Zimmermann, 2014).

In the area of requirements engineering, various recommender systems have been proposed for products including stakeholders, features and requirements (Mobasher & Cleland-Huang, 2011; Felfernig et al., 2013).

An interesting approach using small data with contexts and heuristics called “recommendation in-the-small” was recently introduced and used in software engineering recommendations. (Inozemtseva, Holmes, & Walker, 2014).

A data/knowledge engineering recommender system with relevant constraints as the recommendable knowledge engineering product has been proposed (Felfernig et al., 2013; Felfernig, Jeran, Ninaus, Reinfrank, & Reiterer, 2013).

Recommender Applications in Other Domains

Healthcare is also a promising field for recommender systems. In the healthcare setting, the users are patients and healthcare professionals, and the recommendable items are products such as healthcare-related goods, services or information. Health recommender systems could help patients and healthcare professionals with personalized recommendations of relevant healthcare-related goods, services or information. Health and nutrition recommender systems have been discussed (Wiesner & Pfeifer, 2014; Mika, 2011).

Other proposed emerging application domains include persuasive systems and smart homes (Felfernig et al., 2013).

Recommender technologies will continue to be applied successfully in a variety of novel and interesting application domains.

FUTURE RESEARCH DIRECTIONS

Researchers have proposed a number of extensions to current recommender technologies and outlined

future challenges (Adomavicius & Tuzhilin, 2005; Felfernig, Friedrich, & Schmidt-Thieme, 2007; Felfernig et al., 2013).

Important future trends and research topics include:

- Group recommendations,
- Context-aware recommendations,
- Ubiquitous, mobile and location-aware recommendations,
- Multi-criteria recommendations,
- Cross-domain recommendations,
- Explanations of recommendations,
- Novelty, diversity and serendipity in recommendations,
- Privacy, security, and trust in recommendations,
- New recommendation application domains.

Leading researchers and companies in the field of recommender technologies, and their recent progress, can be found at conferences and in journals. The major conferences are the premier series of Association for Computing Machinery (ACM) Conference on Recommender Systems (RecSys), SIGIR Informational Retrieval, SIGKDD Knowledge Discovery and Data Mining, International Conference on World Wide Web (WWW), and International Conference on Intelligent User Interfaces (IUI). The major journals include ACM Transaction on Information Systems (TOIS), IEEE Intelligent Systems, Expert Systems with Applications (ESWA) and Decision Support Systems (DSS).

Future research will continue to focus on building more effective and efficient recommender systems for a wider range of application domains.

CONCLUSION

We have presented a brief overview of the field of recommender technologies and their emerging application domains. This chapter explains the current major recommender system approaches

within a unifying model, discusses emerging applications of recommender systems beyond traditional e-commerce, and outlines emerging trends and future research topics, along with additional readings in the area of recommender technologies. We believe that personalized recommender technologies will continue to advance and be applied in a variety of traditional and emerging application domains to assist users in the age of information overload.

KEY TERMS AND DEFINITIONS

Collaborative Recommender Systems: Recommender systems that recommend items through user collaborations and are the most widely used and proven method of providing recommendations. There are three types: user-to-user collaborative filtering based on user-to-user similarity, item-to-item collaborative filtering based on item-to-item similarity, and latent factor-based collaborative filtering based on user-item matrix factorization.

Content-Based Recommender Systems: Recommender systems that are based on content of items and recommend a list of items with similar content to that of the items that were given good feedback by the target user.

Electronic Commerce: Activities of a traditional commerce process by using information and communication technologies through the Internet and intranets.

Hybrid Recommender Systems: Recommender systems that recommends items by combining two or more methods together, including the content-based method, the collaborative filtering-based method, the demographic method and the knowledge-based method.

Item-to-Item Collaborative Filtering: Collaborative filtering method that is based on similar items and recommends a list of items that are similar to the items that were given good relevance feedback by the target user.

Latent Factor Model-Based Collaborative Filtering: Collaborative filtering method that is based on latent factor models such as matrix factorizations and recommends a list of items that other user gave relevance feedback similar to that provided by the target user.

Personalized Recommendation Problem: Given a target user, produce personalized recommendations of items such as goods, services or information for the target user.

Recommender Systems (Recommendation Systems): Systems that provide users with personalized recommendations of items such as goods, services or information and thus help users find relevant items in the information overload.

User-to-User Collaborative Filtering: Collaborative filtering method that is based on similar users and recommends a list of items that other user gave relevance feedback similar to that provided by the target user.

D

Use of Data Analytics for Program Impact Evaluation and Enhancement of Faculty/Staff Development

Samuel Olugbenga King
Auburn University, USA

INTRODUCTION

One of the major developments in the 21st century academic development landscape is the pressure to meet “institutional concerns for quality control and accountability” (Land, 2011, p. 175). The now pervasive accountability culture, including a requirement for the use of “much more sophisticated evaluation mechanisms than have been the case in the past” (Brew & Peseta, 2008, p. 84) is typically driven by external accountability pressures. But there are also internal pressures. For example, Brew and Peseta (2008) describe how a change in management of an academic development unit can catalyze fresh demands for a systematic evaluation of the unit’s programs and effectiveness (pp. 83-84). *How might an academic development center that is faced with both external and internal accountability pressures demonstrate the impact and contributions of its programs to the broader institution’s strategic plan?*

To address this challenge, this paper will focus on the use of data analytics to satisfy the twin external and internal accountability demands (*summative evaluation*), while contributing to faculty and staff development in the process (*formative evaluation*). The goal is to meet the “increasing ‘troublesome’ expectations for academic development specialists to demonstrate the impact of their work” (Taylor, 2011, p. 95) through the use of data analytics, which enables systematic evaluation. In the next section, data analytics will be introduced within the context of the broader higher education institutional research ecosystem.

BACKGROUND: INSTITUTIONAL RESEARCH AND DATA ANALYTICS

Historically, the field of institutional research in higher education is predominantly focused on the strategic use of information and data sets to implement, review and enhance the academic mission of the university (Buller, 2012). The types of data that have been collected include system-generated behavioral data, e.g., human resource systems; survey data; transactional data, e.g., learning management systems; and frozen data, e.g., admission head counts (Bichsel, 2012, p. 16). But with the technology revolution, higher education is increasingly adopting and leveraging a range of data systems to support institutional capacity and meet strategic goals. The range of data systems that have been deployed to support higher educational units, such as student enrollment, information technology, budgeting and finance, human resources, student success, research administration, and facilities, include enterprise resource management (ERP) systems or business management/intelligence software, academic enterprise systems (e.g., LMS), customer relationship management (CRM) systems, and personalized learning environments, including assessment software (Norris & Baer, 2013, p. 9). An overview of the data analytics ecosystem in higher education is presented in Figure 1.

Moreover, 69% of higher education institutions surveyed in the USA on the use of data analytics indicated that analytics was either a “major institutional priority” or “major priority for some

Figure 1. Use of data analytics in higher education, with list of providers

departments but not entire institution” (Bichsel, 2012, p. 8). But this is not just an American phenomenon. For example, ERP systems (e.g., Oracle and PeopleSoft) and LMSs (e.g., Blackboard, Moodle and Sakai) are pervasive at institutions in Africa, Asia and Europe (e.g., Cochrane, Black, Lee, Narayan, & Verswijvelen, 2013; Nkurunziza, 2013). This pervasiveness of analytics systems is linked with their perceived benefits for student enrollment and academic success, optimization of the use of institutional resources, and demonstration of higher education’s effectiveness and efficiency (Bichsel, 2012, p. 11). As Petersen (2012) commented, the “current higher education landscape is replete with demands for improving accountability, increasing efficiency, and controlling costs. At the same time, information technologies make it easier to collect and analyze

information to measure outcomes or to assist in decision making” (p. 44).

It is therefore clear from the ubiquity of data analytics in higher education that institutions have adopted them as a systematic tool to measure, support and enhance performance. But this question may arise, *Are there any specific reasons why analytics would be strategically beneficial to academic development?* In the next section, I will highlight the role of data analytics in academic development.

THE ROLE OF DATA ANALYTICS IN ACADEMIC DEVELOPMENT

The field of academic development is evolving, but one of the requirements for further advancement

in the field is the need for the adoptions of tools and concepts that transcend local institutional contexts. For example, Land (2011) advocates the adoption of “new tools of analysis and some conceptual lenses to bring our educational practices into view somewhat differently, so that our understanding of what might be happening can unfold through a variety of perspectives and offer different ways forward” (p. 176). A review of the academic development literature (Gibbs, 2013; Gordon, 2012; Levinson-Rose & Menges, 1981; Ouellett, 2010; Steinert et al., 2006; Stes, Min-Leliveld, Gijbels, & Van Petegem, 2010; Taylor, 2011; Amundsen & Wilson, 2012) indicates that there are three other relevant requirements for further progress in the field:

1. The adoption of conceptual frameworks to help augment the transferability of study findings to similar contexts, e.g., transversal measures – Gordon (2012, p. 177);
2. The need for sophisticated, systematic evaluation; and
3. The need for detailed descriptions of practice to enhance transferability.

The position of this paper is that if data analytics is situated within a coherent theoretical framework and detailed descriptions of its applications are provided, then it is a compelling and systematic tool that can provide summative and formative evaluations of programs’ impact and effectiveness. Data analytics provides sophisticated evaluation mechanisms for academic development because of the following attributes:

- Ability to receive, incorporate and process large sets of data, including in real time;
- Use of advanced algorithms to detect patterns in data for analysis;
- Visualization of datasets (e.g., dashboards, infographics, widgets);
- Provision of big-picture, as well as fine-grained/granular data views;

- Makes feasible longitudinal evaluation, as they serve as data repositories.

The primary focus of this paper is the use of the data analytics system, Google Analytics, to provide summative and formative evaluation of a Center’s programs in response to external and internal accountability demands. But there will also be a secondary focus on the use of data analytics to evaluate the impact or uptake of academic development videos. The next section will highlight the use of Google Analytics within a cohesive framework to provide summative and formative evaluations of the impact of an academic development Center’s programs to meet both external and internal performance demands.

USE OF GOOGLE ANALYTICS AS A KNOWLEDGE PERFORMANCE INDICATOR (KPI)

Although there are different views of data analytics, in this paper, analytics is defined as the “process of data assessment and analysis that enables us to measure, improve, and compare the performance of individuals, programs, departments, institutions or enterprises, groups of organizations and/or entire industries” (van Barneveld, Arnold, & Campbell, 2012, p. 3). Data analytics in essence provides a set of objective key performance indicators (KPIs). This section will detail how Google Analytics, which focuses on the analysis of web site traffic data, is being used to evaluate the performance of a center for teaching and learning at a research university (see Matteson, 2013 for a practical guide to opening a free Google Analytics account).

Google Analytics Application Context: The Biggio Center

The Biggio Center for the Enhancement of Teaching and Learning engages, supports, and empowers

Auburn University's academic community in each phase of the scholarly teaching and transformative learning process. Some of the programs include new faculty and graduate student development, distance learning, testing services, professional development workshops and seminars, instructional technology, and active learning spaces and design. Moreover, the Center's programs are intentionally aligned with the Auburn University's mission and strategic plan. For example, one of the alignment goals is the provision of access to development resources and support throughout the academic career of Auburn faculty and staff. Many of the Center's programs are accessed through its web site, which is often the first point of contact for patrons. So the web site is integral to the operational effectiveness and impact of the Biggio Center.

The Biggio Center faces two accountability measures. The external accountability demand reflects the new accountability culture in higher education. The Center is required to produce annual reports that show how its programs are contributing to the wider university's strategic plan. Brew and Peseta (2008) highlighted how annual reports can be used to "establish the impact of academic work" (p. 83). In addition, the Center is under new management that is interested in reviewing past performance in order to consolidate and modify practices, so as to assure continued enhancement and progress (Gray & Radloff, 2008). So an evaluation of its web site traffic is invaluable to satisfying both internal and external requirements for impact evaluation and improvement. The results of the Google Analytics evaluation process are therefore designed to satisfy both the external demand, which is summative in thrust, and the internal requirements for improvement, which is quintessentially formative.

Moreover, the academic development literature furnishes several notable examples or potential applications of data analytics. For example, the authors of the study reported in Cochrane et al. (2013) used information from data analytics (#web

clicks per student) on the low learner engagement on the e-learning courses hosted on Blackboard at "New Zealand's largest polytechnic" (p. 276) to change the institution's e-learning strategy by re-orienting the courses from a teaching-centered to a learner-centered pedagogy through the implementation of communities of practice (pp. 276-277). The analytics indicated that "fewer than 40 of the over 1000 courses on Blackboard in 2004 evidenced interactivity beyond discussion boards" (p. 277).

Howard (2012) highlighted the value of "YouTube Universities" (p. 168), e.g., The MIT YouTube Channel, and implicitly linked the corresponding YouTube video analytics data as a measure of diffusion and impact. Similarly, Rhode and Krishnamurthi (2013) describe how they used tracking data analytics of the database system designed for faculty consultations to improve faculty development consultation services. On a broader scale, impact factors and citation counts are used as measures of journal prestige and faculty productivity respectively.

THE ANALYTICS PROCESS

The cohesive framework that has been adopted to guide the use of Google Analytics in the impact evaluation of the Biggio Center's web site is the *analytics process* (Figure 3), which entails five components:

1. Starting with a strategic question;
2. Finding or collecting the appropriate data to answer that question;
3. Analyzing the data with an eye toward prediction and insight;
4. Representing or presenting the findings in ways that are both understandable and actionable, and
5. Feeding back into the process of addressing strategic questions and creating new ones.

Figure 2. The Biggio Center web site home page

Figure 3. A pictorial overview of the analytics process
Adapted from Norris & Baer, 2013, p. 53.

Figure 4. Composite data about the web traffic and users of the Biggio Center Web site

The strategic questions that were adopted and that Google Analytics has been used to investigate are:

1. What can be learned from the Biggio Center web site traffic about the uptake or usage (i.e., impact) of the Center's programs and services?
2. How may the findings be used to reinforce, modify, or enhance the Center's programs and services?

The next section will detail how these questions have been answered through Google Analytics.

Overview of the Uptake of the Biggio Center's Programs

The *line graph* in Figure 4 shows there was a total of 32,140 sessions or visits to the Biggio Center site by 23,855 visitors between September 1, 2014 and March 25, 2015. The peak period, with about 6,000 visits, was in January, 2015. This means that 121 people visited the web site per day in the period under review. Meanwhile, the number of total Auburn University employees who may be

realistically expected to benefit from the Center's programs is about 4000.

The *pie chart* shows that nearly 28.9% of the total number of sessions were by *returning visitors*. This is perhaps an indication that the Biggio Center has a significant footprint in the Auburn University community and that patrons have high satisfaction with the level of programs offered. Further, the fact that seven of out 10 visits (71.2%) to the Biggio Center site is by *new visitors* indicates that the Center's programs are perhaps attractive to new clients.

The *areas of improvement*, based on this composite dataset overview, include reducing the bounce rate (49%), the number of people who leave the web site without any further interactions, and perhaps increasing the average session duration beyond 1:55 minutes. The peak period in January 2015 coincides with a major center initiative (a large professional development event), while the dip in December 2014 is understandable in a higher education context – there is a lull in programming, and a winding down of the academic calendar for the year.

One way to leverage the peak data is to create longitudinal anchors to the audience for the

Figure 5. How users found or were directed to the Biggio Center site

large event in January. For example, Gibbs (2013) describes how the “most important consequences of training of newly appointed teachers is not that they teach better in the classroom the next week, but that some come back to the educational development unit for help a decade later when they eventually become head of department” (p. 8). So the challenge is to create meaningful programming that would catalyze the ‘coming back’ of program participants both in the short term, and over the duration of their careers.

Mode of Site Navigation

The data in Figure 5 indicates that nearly six out of the 10 people (59.6%) who accessed the Biggio Center site did so *directly*. This includes typing the url directly into the browser, and also accessing the site through links in emails and relevant Biggio Center program applications. Similarly, at least one out of three people (35.9%) found the Biggio Center site through organic search, i.e., the use of search engines such as Google and Bing, either to navigate directly to the Biggio Center site, or by searching for similar services and programs.

Another possible area for improvement would be to include the program schedules or events calendar prominently on the Center’s home page, so that visitors would not have to navigate a couple of web pages before accessing the program schedule.

The *areas of improvement*, based on this channel dataset, includes correlating the peaks and troughs in web traffic (Figure 4) with how users navigated to the web site, as depicted in Figure 5. For example, since most users find the site directly, including the Center’s url in informational and program literature, and incorporating QR codes would facilitate easier navigation to the site. This is buttressed by the fact that the direct search traffic is positively correlated with the overall web traffic to the Center site (Figure 6). Social media contributes less than 1%, so it is not considered important as a source of traffic.

Use of Mobile Devices

The Biggio Center recently optimized its web site to ensure mobile accessibility, so an overview of which devices are used to access the web site is relevant. The data in Figure 7 indicates that about

Figure 6. Contributions from Direct and Organic Search to the total web traffic

Figure 7. Percentage of visits to the Biggio Center web site via mobile devices

29% of visits to the site were through mobile devices (mobile phones and tablets).

Similarly, the data in Figure 8 shows that the top mode of navigating to the Biggio Center site is through the use of a desktop via direct navigation. In contrast, visitors who use a mobile phone to access the site are slightly more likely to do so via organic search (11.2%) than directly (9.6%). Further, tablet users clearly prefer navigating to the site directly (5.2%) rather than through organic search (1.9%).

Meanwhile, the data in Figure 9 shows the top 20 web pages that are visited on the Biggio Center web site. The most visited Center programs are the Distance Learning pages, including the Dietary Managers Program, and Testing Services.

Another perspective on visitor behavior on the Biggio Center site is to look at persistence – if visitors do not find what they really need on the landing page, for example, they might keep browsing till they get to the right web page. For example, the data in Figure 10 presents information on the third web pages (“2nd interaction”) that visitors navigate to after beginning their browsing from the “starting pages”. Again, the most visited web pages are the distance learning pages (13,200 sessions or about 42% of all sessions). An interesting data point for the 2nd interaction dataset is the fact that the Center’s Spring 2015 program schedule (“/ACADEMIC/spring2015”) seems to be valued by some of the visitors.

Figure 8. Correlation of device use with navigational mode patterns

Figure 9. The top 20 most visited web pages on the Biggio Center web site (the type of device, mobile or desktop, used to access the site is also linked)

Device Category		Landing Page	Sessions	Sessions
			32,140 % of Total: 100.00% (32,140)	32,140 % of Total: 100.00% (32,140)
1.	desktop	/biggio/distance-learning/	9,151	28.47%
2.	desktop	/biggio/	2,872	8.94%
3.	mobile	/biggio/distance-learning/	2,746	8.54%
4.	tablet	/biggio/distance-learning/	1,278	3.98%

The *areas of improvement*, based on the datasets presented in Figures 7-10, include brainstorming on whether it might be feasible to increase the social media traffic to the site. For example, the videos on the Biggio Center YouTube site have been viewed 6567 times (i.e., between February 2010 and April 2015). In contrast, there were only three visits from the YouTube traffic to the main Biggio Center web site. So there is no correlation between levels of activity on the Center's YouTube site and the traffic from the YouTube site to the Center's main web site. Further, there is scope to perhaps considerably enhance the electronic registration process for the Testing Services program, which currently includes a significant offline registration process. It would also be beneficial to post updates for the Distance Learning courses

and Testing Services on the home page to provide easier navigation aids for visitors.

In summary, the data clearly shows that there is significant web traffic on the Biggio Center's web site, which is an indication of update and usage levels. It is also clear that the most valued resources appear to be the Distance Learning courses, Testing Services, and to a lesser extent, program schedules.

It would be important to benchmark this dataset (September 2014 – March 2015) with future longitudinal datasets to more precisely evaluate the uptake of the Biggio Center's programs and services by the Auburn University community and other relevant stakeholders.

Figure 10. Mapping user behavior from the initial “starting pages” to the third page (“2nd interaction”)

ADDRESSING DISADVANTAGES OF USING DATA ANALYTICS

It is important to address the potential disadvantages of using Google Analytics or a similar data analytics system (KPIs) for summative or formative program evaluation. Some of the potential pitfalls associated with the use of data analytics include cost, data misuse, inaccurate analysis or findings, the relevance of the data analytics approach, and privacy (Bichsel, 2012; Oblinger, 2012; Stiles, 2012; van Barneveld et al., 2012).

These pitfalls have been mitigated in this study through the adoption of Google Analytics, which is free, with its use situated within the analytics process, to constructively align data collection and analysis with the larger external and internal program impact evaluation requirements. Data triangulation has also been adopted to corroborate the findings from Google Analytics. For example,

the peaks and troughs for the line graph in Figure 4 were corroborated with the information about the Center’s program schedule for December 2014 and January 2015. The data analysis has also focused on a seven-month period, which provides better data aggregation.

To assure user privacy, no individual or user identification has been collected or monitored through the Google Analytics process. The analysis has instead focused on the investigation of broad trends, which necessarily involves the masking of user identification data. So the manner of adoption of Google Analytics for this study could be construed as low “reputational risk” (Figure 11), as it is geared towards the protection of user identity.

Finally, the appropriateness of the use of Google Analytics for this study could be filtered through the five dimensions or benchmarks of good ass

Figure 11. Data sensitivity classification

Adapted from Stiles, 2012, p. 24.

	Most Critical <i>Highest level of sensitivity</i>	Critical <i>Moderate level of sensitivity</i>	Least Critical <i>Very low, but still requiring some protection</i>
Legal requirements	Protection of data is required by law (e.g., HIPPA and FERPA data elements and other PII protected by law)	The institution has a contractual obligation to protect the data (e.g., bibliographic citation data, bulk licensed software)	
Reputational risk	High	Medium	Low
Other institutional risks	Information that provides access to resources, physical or virtual	Smaller subsets of Most Critical data from a school, large part of a school, or department	
Data examples	Medical Student Prospective student Personnel Donor or prospect Financial Contracts Physical plant detail Credit card numbers Certain management information	Information resources with access to Most Critical data Research detail or results that are not Most Critical Library transactions (e.g., catalog, circulation, acquisitions) Financial transactions that do not include Most Critical data (e.g., telephone billing) Very small subsets of Most Critical data	Campus maps Personal directory data (e.g., contact information) E-mail Institutionally published data

essment rubric (Suskie, 2006). The use of the free Google Analytics software has been driven by the adoption of *strategic questions and goals*, which have provided *reasonably accurate and truthful results*, and which have in turn provided *valuable* summative and formative evaluation to feed into the iterative process of program,

reinforcement, modification and improvement (Figure 12).

Hence the analysis of the Google Analytics findings has been guided by the need to combine “analytics with sound reasoning” (Oblinger, 2012, p. 12).

ANALYTICS (KPIs) FOR ACADEMIC DEVELOPMENT VIDEOS

Many academic development centers increasingly produce and integrate videos into their programs and services, which are typically hosted on sites, such as YouTube, Vimeo, or Kaltura. So one way to assess the analytics on the Biggio Center academic development digital videos is to benchmark the data with the digital videos produced by other academic development centers. The examples provided (Table 1) are therefore further data points about measuring comparative impact (van Barneveld et al., 2012), as they help provide a big picture view regarding the use and uptake of academic development videos in the United States and Canada.

This big picture view can also be extended to other geographical regions in order to provide international benchmarking of academic development videos. For example, digital video analytics for academic development centers in the United Kingdom, Singapore and Australia is provided in Table 2.

FUTURE RESEARCH DIRECTIONS

Future research will focus on comparative studies of analytics applications (e.g., Tableau and iDashboard), as well as an longitudinal evaluation of the impact of the use of data analytics on the programming efficacy of academic development centers.

CONCLUSION

This chapter has focused on how academic development centers may respond to the twin demands of internal and external pressures for demonstrations of impact and effectiveness, especially within a higher education context that is increasingly defined by an accountability culture. The focus has been on the use of data analytics based on its unique affordances to provide cost-effective, systematic, reliable and useful data to inform both summative and formative evaluation. The data analytics process has been conducted by situating the inquiry within a cohesive framework of strategic questioning and analysis.

The data analytics process has been applied to evaluate the impact of the programs of an academic development center (i.e., the Biggio Center) at a large research university, with the findings being filtered to enhance further development at the center. The findings from the center have also been benchmarked with data from similar centers in North America to provide a big picture overview of the emerging field. Similar comparisons have been provided for institutions in Europe, Australasia and Africa. Moreover, the data analytics process reported in this study has been designed to enrich the academic development field regarding the need for systematic evaluation of impact, detailed descriptions of practice to enhance generalizability, and the adoption of new tools of analysis to advance understanding in the field. Further, the potential pitfalls about using data analytics, including privacy, have been addressed.

It is astute to conclude that the revamped accountability culture in higher education and the associated troublesome expectation regarding “performance measurement is not going to go away”. Therefore one way to respond to the new pressures is by embracing a data-driven culture (Bichsel, 2012) that prioritizes the use of knowledge performance indicators, such as Google Analytics and YouTube Video analytics, as a way

to both demonstrate impact and enhance further development. This approach would guarantee a blending of higher education “accountability and assurance agendas more explicitly into our narrative” (Stefani, 2013, p. 296), so as to meet and exceed the troublesome expectations in stride.

ACKNOWLEDGMENT

The author wishes to acknowledge his gratitude to Dr. Diane Boyd for the helpful critique provided on the initial draft of this manuscript.

KEY TERMS AND DEFINITIONS

Academic Development Center: The Centers at universities and colleges whose primary purpose is to support the professional development of faculty, staff and graduate students.

Accountability Culture: The significant push for quality measures and/or data metrics as evidence of a higher education unit's effectiveness.

Analytics Process: The pedagogical alignment of the use of data analytics software to address specific (identified) objectives, such as faculty development or student learning goals.

Data Analytics: The use of specialized software to analyze large datasets to provide actionable feedback or information.

Formative Evaluation: Assessment that is intrinsically used to inform, develop or shape both process(es) and product(s).

Knowledge Performance Indicators: Specialized programs or data metrics that provide quantifiable measures or indicators of performance.

Summative Evaluation: Assessment with primary focus on final outcomes or product(s).

Corporate Disclosure Measurement

Md. Salah Uddin Rajib

Jahangirnagar University, Bangladesh

Md. Qutub Uddin Sajib

China University of Geosciences (CUG), China

INTRODUCTION

Researchers have mentioned that about 90% of the entire world's data has been created in the past 2 years (e.g., Kolb & Kolb, 2013). Most of these data are made in electronic format. Corporate disclosures (CDs) are available now in electronic formats through different documents also. As the organizations are disclosing the disclosure annually or in the interim period, the numbers of volumes are increasing gradually. Organizations disclose disclosure through various media, e.g., annual reports, websites, supplementary of financial statements and others.

A number of researchers have investigated the corporate disclosure (CD) scenario in the last decades as it is assumed to have an impact on the capital market (Healy & Palepu, 2001). CD can be categorized into two broad groups – Mandatory disclosures and Voluntary disclosures. Mandatory disclosures are obligatory by the concern organization of a country (e.g., Securities and Exchange Commission). In contrast, voluntary disclosures are made by the firms voluntarily considering the interest of stakeholders. A number of topics on CD have been investigated e.g., financial disclosure (e.g., Malone et al., 1993), human resource capital (e.g., Bontis, 2003), environmental disclosure (e.g., Gamble et al., 1996), strategic disclosure (e.g., Wagenhofer, 1990) and others.

Very often, researchers have used content analysis to explore the scenario of CD practice (e.g., Bontis, 2003; Khan et al., 2011). In content

analysis they normally count the frequency of words to explore the scenario. Researchers normally select a list of related terms or keywords to the concern topic and search the terms in the annual reports or other related supplementary where disclosure has been presented by the organizations (e.g., Bontis, 2003).

Researchers have urged for more reliable measurement of CD practice (e.g., Rahman & Post, 2011). Consistent with that, this chapter proposes the use of text mining (TM) approach for measuring the CD. Currently, different areas of researches are applying the approaches and techniques of TM. Researcher of medical science, politics, business and others have used the techniques of TM to extract the information (Moohebat et al., 2015). The purpose of TM is to process unstructured textual information. In large text collection, TM works as a tool for knowledge discovery (Gomez et al., 2002). TM uses several techniques to extract the information, e.g., text classification, text clustering, text summarization, sentiment analysis and others. This chapter investigates the usability and advantages of TM approaches in the measurement of CD. Therefore, the aim of this paper is fourfold. First, it reviews the background of CDs and their measurement and background of TM. Second, it discusses the TM approaches, including general model of TM and methodology. Third, the usability of TM in measuring the CD has been investigated. And finally, it discusses the prospects of research in the area of using the TM in CD measurement.

BACKGROUND

As mentioned earlier, CD can be categorized into two broad groups - mandatory and voluntary disclosure. The demand for CD primarily arises from the perspective of regulation. Therefore, Securities and Exchange Commission (SEC) played an important role in the CD, made by the organizations. History states that because of various crises in US e.g., war, unemployment, racial conflict, environmental degradation and others, authority tempts to examine the fundamental principles underlying the body of corporate law for policy making (Schoenbaum, 1972). Sarbanes-Oxley (SOX) requires more and better information also. Consisting with the situation The Securities Exchange Act of 1934 imposes disclosure requirements on corporations in the US (Schoenbaum, 1972). With time, Generally Accepted Accounting Principles (GAAP) imposes some disclosures on corporations. Voluntary disclosure drives by various factors, e.g., manager-specific influences (e.g., Bamber et al., 2010), corporate governance (e.g., Hermalin & Weisbach, 2012), external pressure groups (e.g., Islam & Deegan, 2010) and others. Therefore, voluntary disclosures are associated with various areas and it is unstructured in nature. Researchers have tempted to find out the relationship of CD with the organization performances (Healy & Palepu, 2001). Therefore, measurement of CD emerges as a research area for the researchers.

This chapter conducts studies on the usability of text mining (TM) for CD measurement. TM is a discipline of natural language processing. The approach of TM has evolved from the simple word processing at the end of the 1990s to now (Antonio & Ferneda, 2008). TM derives much of its inspiration and direction from seminal research on data mining (Feldman & Sanger, 2007). The increased numbers of electronic documents have triggered the use of TM to extract the knowledge from textual data.

TEXT MINING: GENERAL MODEL AND METHODS

The primary objective of TM is to retrieve information from unstructured text and to present the extracted knowledge to the users in a concise form (Ananiadou & McNaught, 2006). It has been mentioned by the researchers that TM can add significant importance and economic value where the data are in electronic form and are in centralized warehouses (e.g., Weiss et al., 1999).

Text Mining (TM)

TM is defined as a tool for extracting the information from electronic documents by using natural language processing computer program. Broadly, TM can be defined as a knowledge-intensive process in which a user interacts with a document collection over time by using a suite of analysis tools (Feldman & Sanger, 2007). Like the data mining, TM extracts useful information from the sources through various approaches. It can collect data both from formalized database records and from unstructured textual data.

General Model of Text Mining

In a TM technique, computer programs scan text in a document and apply model consisting with the objective. The individual documents are used as raw cases for TM. The basic approach of TM can be shown by the following figure -

Figure 1 shows that the documents assemble directory drive from the documents that are raw cases for the TM techniques. After representing the text in the computerized program, the features of the text will be extracted. After extracting the feature, various pre-specified models can be applied. The frequency of the terms can be counted easily or document can be classified considering various aspects.

Figure 1. A general model of automated text mining
Adapted from Weiss et al., 1999.

Methods of Text Mining

There are various methods for TM and TM related tasks. The developments of data mining and computer program are enriching the TM regarding the methods and approaches (e.g., Billheimer et al., 2003). Considering the objective of this chapter, several common methods of TM have been discussed below. It seems that methods like Term identification, Document Clustering, Document Summarization and Automated Document classification will be helpful for measuring the CD practice.

Term Identification

Term identification is known as keyword identification also. Keywords are widely used to define queries with information retrieval systems as they are easy to define, revise, remember, and share (Rose et al., 2010). Generally the keywords or the keyterms represent the essence of a document. Terms or the keyterms are used by the researchers from the very beginning of measuring the CD practice.

The use of the keywords or the terms is visible in numerous areas. Therefore, Automatic term recognition (ATR) has received concentration of the researchers. ATR can be defined as a technique which automatically identifies and extracts terms from the text. For ATR, there are various methods arises from the different approaches

like rules based, co-occurrence-based, statistical and machine learning techniques (Ananiadou & McNaught, 2006).

The ATR method provides a number of important features that are beneficial for various aspects. For example, ATR can recognize the ‘multi-world terms’ or ‘nested terms’ efficiently (Frantzi et al., 2000). By handling the primarily extracted terms from a document efficiently, the performance of ATR can be improved more. Acronyms, inflections, orthographic variants can be handled easily on primary extracted terms of TM through screening. It is natural that in a text document, one term will not present the same realization through the entire document. TM can handle these issues efficiently through various ways.

As an example of TM, texts have been extracted from the annual reports (for 2013) of the nine largest chemical companies (BASF, Dow Chemical, Bayer, Saudi Basic Industries, LyondellBasell Industries, E. I. Du Pont de Nemours, Air Liquide, Syngenta, Praxair) of the world. The screenshot (STATISTICA, version 8 has been used) has been presented in Figure 2.

Document Clustering

Document clustering or text clustering involves with the clustering or making groups of textual documents regarding various objects. It is used to classify the documents. The TM technique can perform the document clustering consider-

Figure 2. Text extraction from the annual reports of 9 largest chemical firms in the world

ing the intended use. A group of documents can be clustered as topic clusters, corresponding to a topic shared by all the documents included in the cluster (Thomas et al., 2011). In TM approach, there are a number of ways to cluster the documents (Aggarwal & Zhai, 2012). The documents can be clustered regarding a single term i.e., the documents can be clustered weighing the existence of a term frequency. Bag-of-words approach is used to cluster the document also. The bag-of-words approach uses the words of the documents and their frequencies of occurrence within a document in order to identify the central topic(s).

Automatic Document Classification

Automatic Document Classification involves with the automatically categorizing the digital documents into pre-defined class. Automatic document

classification identifies the underlying patterns and distinguishing features within documents that make them part of a defined group or class and uses this information to assign each new document to a known class (Thomas et al., 2011). There are many approaches for automatic document classification (Feldman & Sanger, 2007) e.g., neural networks, Bayesian logistic regression, probabilistic classifiers, regression methods and others. For executing automatic document classification, four main issues have to be ensured (Feldman & Sanger, 2007). First, the categories that will be used to classify the instances must be confirmed. Second, a training set for each of the categories has to be ensured. Third, features that represent each of the instances have to be confirmed. Finally, one should take a decision on the algorithm that will be used for the categorization. By applying the

automatic document classification one can easily classify a new document regarding the developed automatic classifier.

Document Summarization

Radev et al. (2002) have defined summary as a text that is produced from one or more texts, that conveys important information in the original text(s), and that is no longer than half of the original text(s) and usually significantly less than that. It derives from single or multiple documents and will be presented in a useful, and in short form. Document summarization arises from the assumptions, such as– a human reader breaks each sentence into a set of information fragments to which the sentence is referring; information fragments are mutually independent; and an information fragment has an important score (Radev & McKeown, 1999). There are various techniques of document summarization e.g., extraction, fusion, abstraction and compression.

Extraction is the procedure of identifying the important sections of the text and producing them verbatim. Abstraction aims to produce important material in a new way. Fusion combines the extracted parts coherently. And compression aims to throw out unimportant sections of the text (e.g., Radev & McKeown, 2002). Document summarization excludes redundant information scattered across the document(s) and can order the extracted sentences according to chronological relatedness of topic or precedence (Barzilay et al., 2002).

DISCUSSION ON TEXT MINING IN CORPORATE DISCLOSURE MEASUREMENT

In different areas, TM has been suggested in different implementation path. For example, Thomas et al. (2011) show the way of using TM for systematic reviews of literature. The previous research in the area of CD measurement indicates that

the measurement has been executed on the basis of simple content analysis where the frequency of keywords has been counted as the scale (e.g., Bontis, 2003; Khan et al., 2011). This approach can present misleading result very often, as it does not consider the position of words in the sentence and the meaning of the sentence. After discussing the basic approaches and methodologies, it seems plausible that TM can be used for CD measurement and it can produce more reliable results. Figure 3 has been presented to show the area where TM can be used in CD measurement.

Figure 3. Corporate disclosure measurement and area of text mining

Adapted from Thomas et al., 2011.

Text Mining Technique for Corporate Disclosure Measurement

In this section, different features of TM have been investigated to check the usability of TM for CD measurement. The discussion has been executed within four main methods of TM. 1) Term identification, in which keyterms from documents are identified automatically; 2) Document clustering, in which similar documents relating to the CD can be grouped together; 3) Automatic document classification, which can classify the documents automatically regarding the CD in terms of keywords and 4) Document summarization, which can ensure the quality of CD measurement by extracting the salient informative components of documents. Discussion has been arranged below considering the stage of application of TM.

Identifying the Relevant Document

To measure the CD practice of an organization, it is plausible to consider all the documents that are published by an organization. A number of previous researches have used annual reports only to measure the practice of CD (e.g. Gamble et al., 1996; Bontis, 2003). But, the organization publishes a number of electronic documents in a year, e.g., annual report, brochure, interim reports, and different memorandum. Moreover, publication of information through the website is a common practice nowadays.

Searching all the documents that are published by the organization is time consuming under the manual approach. Under this situation, TM can play an important role. TM offers a number of advantages to measure the CD. Firstly, researchers will be able to investigate a wider context in a shorter time. Secondly, this alternative approach will enrich the research methodology and will contribute to the development of reliable measurement of CD. It will contribute to the urge of demanding transparency and reliability for the measurement of CD (e.g., Rahman & Post, 2011).

Identification of Terms

One of the challenges in CD measurement is to select the search term. Previous research on CD measurement shows that over the years, researchers have developed indices to measure relevant area's CD (Marston, 1991).

TM can offer a broader scope for the identification of terms. Apart from the index terms, researchers can investigate the possible terms for inclusion in the measurement of CD by using the TM. The range of search terms will be much wider that will increase the reliability of CD measurement.

Identification of keyterms has two main characteristics. Firstly, it expands the scope of identifying the terms. Secondly, the cross-disciplinary terms will not be recognized efficiently. These features are effective for the CD measurement also. The automatic term identification of TM expands the scope for term identification to measure the CD. But, the cross-disciplinary terms will not be recognized efficiently. For example, voluntary disclosure which is unstructured in nature may include 'environmental concern' whereas some documents may recognize it by 'ecological concern'. Therefore, further processing is needed for efficient measurement of CD after automatic term identification.

Screening the Term and Screening Prioritization

The limitation of automatic term identification that has been mentioned in the previous section (e.g., cross-disciplinary term) demands screening the term.

To screen the term manually, very often two people are employed (Thomas et al., 2011). This labor-intensive task consumes considerable amount of cost and time. To reduce the time and cost in screening, automatic classification has been suggested (e.g., Thomas et al., 2011). The approach of automatic classification is applicable

for the measurement of CD also. At first, automatic classification can tell whether the documents are going to disclose financial issues, ecological issues or human resources developmental issues. Reviewing the documents after classification can reduce both the cost and time and ensure the reliability at the same time. Mandatory corporate disclosure, e.g., legal issues can be identified easily by screening.

Basically, researchers have suggested two approaches in TM that can help for screening. One is automatic document classification and another is the use of term recognition technique under screening prioritization.

When it is not possible to use automatic classification, the term recognition technique under screening prioritization may be a workable alternative (Thomas et al., 2011). For the use of term recognition, relatively little ‘training’ of the system is required. The term can be identified and weighted considering the degree of relevance with the specific CD. Then, a certain percentage of keywords of the lists can be checked manually for erroneous exclusions.

Screening can provide archival benefit by identifying the most relevant documents. This retrieval features will enhance the reliability of CDs measurement. Situation of multi-words can be handled efficiently by screening also. But, screening has limitations. There is a chance that researcher will be failed to quantify the number of terms or documents that have been missed in the screening (Thomas et al., 2011).

Applying Eligibility Criteria

Applying eligibility criteria is another approach for TM that has been suggested by the researchers for the information extraction from documents (e.g., Thomas et al., 2011). Under this approach, researchers identify a set of relevant titles and abstracts manually in order to train a classifier. Then the developed training set is used for the remaining relevant studies. This approach is fruitful when the numbers of documents are large and

increasing frequently. This approach is applicable for measuring the CD and can offer significant benefit as the documents for CDs are increasing rapidly nowadays.

Applying Pre-Existing Keywords Automatically

It has been found that the researchers have developed indices over the years to measure the CD (Marston, 1991). Therefore, the developed indices can be used easily by TM to measure the CD. Under this situation, TM can add value to the measurement of CD than general search as TM can help for mapping the plural words into their singular form (e.g., human resources and human resource).

Pattern Identification for Documents

TM can identify the pattern of documents weighing the trained data set or from the data set from bag of words approach. Pattern identification for documents method can identify groups of similar documents very quickly. Pattern identification for documents is named as document clustering also. Pattern identification for documents can provide valuable information in measuring the CD. As organizations publish CDs in various documents, pattern identification can be an effective tool for CDs measurement.

Summarizing the Documents

There are two types of document summarization. They are– 1) involves with the extracting important information from documents and 2) formulate a new document by paraphrasing the content of source document(s) (Thomas et al., 2011). Document summarization is applicable for the measurement of corporate disclosure also. Although advanced language generation technique is required for the second method, the first method can be used for the CD measurement easily. It can present the concise form of a document or

multi-documents by redundancy reduction and by ensuring the chronological order. For CD measurement, it can concise the relevant part of specific disclosures and can help the researchers to explain the nature of disclosures for different documents and organizations.

Utility of Text Mining in Corporate Disclosure Measurement

Most of the disclosures made by organizations in various sources are unstructured in nature. Under this situation, text mining can offer great advantages to the researchers for CD practice measurement.

Most of the research papers on the corporate disclosure measurement use different terms or keywords to measure the corporate disclosure. Use of terms or keywords is a good practice for the established theories and for structured texts. However, term based methods suffer from the problems of polysemy and synonymy (Zhong et al., 2012). The situation of 'Polysemy' rises when a word has multiple meanings. And situation of 'synonymy' rises when multiple words have the same meanings.

The probability of the problem of polysemy and synonymy is high for measuring the CD by keywords as the disclosures (especially voluntary) are unstructured in nature. These problems can be partially solved by the TM approaches by extracting the universal words of a document. By using the different TM approaches researchers can hold the sentence flavor also.

Therefore, theoretically it seems that the text mining can add value to the measurement of corporate disclosure which ultimately will impact positively on good business practice.

Summary of Methodology of Text Mining for Corporate Disclosure

The summary of technique of TM that has been discussed for the CD measurement is presented in Table 1. The development of Table 1 is in-

fluenced by Thomas et al. (2011). One notable thing that has been mentioned in the discussion is that some of the techniques of TM can be used individually where some can be used as associate techniques of others. For example, screening techniques can be used after identification of the terms from documents to ensure the appropriateness of measurement.

The efficient use of these methodologies depends on the researchers also. It has been mentioned by the researchers that ethical issues are inherent in the research (Rajib & Mou, 2014).

FUTURE RESEARCH DIRECTIONS

The use of TM in the measurement of CD is relatively new. Therefore, this area has miles to go. New innovations move through a series of stages from learning about the potential of a given innovation, through being persuaded to consider its potential, deciding whether to try it out, trying it out, and deciding whether or not to continue to use the innovation (Rogers, 1983). The proposed measurement of CD by TM is not an exception of this mentioned innovation. This paper develops the concepts only. It discusses the theoretical ground for the use of TM in the measurement of CD. Theoretically, it seems that TM can add value to the measurement of CD in great extent. In future, usability of TM in the measurement of CD can be tested considering various areas e.g., financial disclosure, human resources development, environment concern and others. The results of TM approaches can be compared with the previous research on CD measurement which is based on the simple content analysis.

The techniques of TM are still in the stage of development and evaluation. The methods are still relatively unknown and unused in the area of CD measurement. Therefore, use of TM in the measurement of CD can be investigated from various viewpoints in future.

Table 1. Summary of text mining for corporate disclosure measurement with advantages and disadvantages

Stage of Measurement	Text Mining Method	Advantages	Disadvantages/Limitations
Identification of search terms or keywords	Term recognition	Enriches the search terms and strategy.	More consciousness is required.
Screening the term	Term recognition	Provides the advantages of adjusting the cross-disciplinary terms, multi-terms and others. Reduces the necessity of manual 'double screening' by human beings.	Consciousness is required.
Applying eligibility Criteria	Automatic classification	Reduces the time to select the search term and for final search.	Further development is needed in this technique (e.g., Thomas et al. 2011).
Applying pre-existing keywords automatically	Automatic extraction and Automatic classification	Indices are available in literature of CD measurement practice. By using the previous indices, one can easily extract the frequency of the terms in document(s). By using the previous indices, one can easily classify the documents also.	Using the indices only will reduce the scope of inserting alternative words. Ultimately, it will reduce the reliability of measurement.
Pattern Identification of Documents	Automatic classification	Reduces the time to understand the nature of documents regarding the targeted CD measurement.	Depends on content of documents. It cannot explain critical concepts.
Clustering	Automatic document clustering	It gives an overview of the collection of documents to the researchers quickly.	It cannot recognize complex concepts that need explanation.
Summarization	Summarizing the documents	It can provide a quick summary for a document or for collection of documents from salient informative sentences.	It's not a good technique for the document(s) which content is heterogeneous.

CONCLUSION

Researches in the area of CD measurement are increasing in these days. The documents in which CD is searched are increasing in volume. Searching the CD in general approach is cumbersome. Moreover, the unstructured (especially voluntary disclosure) disclosure makes the measurement difficult.

Probably, the positive news under this scenario for the researchers is that most of the documents are available in electronic format nowadays. TM can be a helpful tool for the researchers to measure the CD in this emerged situation. It can reduce time and cost and can enhance the reliability. By the help of TM, researchers can identify the key-terms automatically as well as search the indexed terms in documents in the shortest time. It can categorize the documents from a large number of documents and helps to present the summary

of documents automatically. As the technology of TM is developing till now, it is expected that further development of text mining will increase the reliability of CD measurement.

KEY TERMS AND DEFINITIONS

Bag-of-Words Model: In this approach a text is considered as the bag of its words. The frequency or occurrence of each word is used as a feature in Bag-of-Words model to classify the documents.

Corporate Disclosure: Financial and non-financial information of organizations those are disclose to the public.

Mapping: Describing the characteristics of the studies that have been explored by the researchers.

Nested Terms: “Nested terms” is a concept to present the joint generalization of words.

Stemming: The term stemming refers to the reduction of words to their roots so that different grammatical forms or declinations of verbs are identified and indexed as the same word.

Training Set: A training set is a set of words that is used to discover potentially predictive model in text mining.

Data Mining and Knowledge Discovery in Databases

D

Ana Azevedo

Polytechnic Institute of Porto, Portugal

INTRODUCTION

The term knowledge discovery in databases or KDD, for short, was coined in 1989 to refer to the broad process of finding knowledge in data, and to emphasize the “high-level” application of particular Data Mining (DM) methods (Fayyad, Piatetski-Shapiro, & Smyth, 1996). Fayyad considers DM as one of the phases of the KDD process. The DM phase concerns, mainly, the means by which the patterns are extracted and enumerated from data. Nowadays, the two terms are, usually, indistinctly used.

Efforts are being developed in order to create standards and rules in the field of DM with great relevance being given to the subject of inductive databases (De Raedt, 2003) (Imielinski & Mannila, 1996). Within the context of inductive databases a great relevance is given to the so called DM languages.

This chapter presents a comprehensive introduction and summary of the main basic topics and bibliography in the area of DM, nowadays. Thus, the main contribution of this chapter is that it can be considered as a good starting point for newcomers in the area.

The remaining of this article is organized as follows. Firstly, DM and the KDD process are introduced. Following, the main DM tasks, methods/ algorithms, and models/patterns are organized and succinctly explained. SEMMA and CRISP-DM methodologies are next introduced and compared with KDD. A brief explanation of standards for DM is then presented. The article concludes with possible future research directions and conclusion.

BACKGROUND

In recent years, we have witnessed the growth and consolidation of the DM area. Since the first Workshop, IJCAI-89 Workshop on Knowledge Discovery in Databases, which took place at Detroit in 1989 and that led, in 1995, to the nowadays main annual conference in the area, ACM SIGKDD International Conference on Knowledge Discovery & Data Mining, the number of publications and conferences dedicated to the area presents a significant growth. These conferences as well as several seminal papers, helped in the consolidation of the area. Since then, the evolution has been overwhelming, and DM can be considered as a consolidated research area (Azevedo, 2015).

DATA MINING AND THE KNOWLEDGE DISCOVERY IN DATABASES PROCESS

“The KDD process, as presented in (Fayyad, Piatetski-Shapiro, & Smyth, 1996), is the process of using DM methods to extract what is considered knowledge according to the specification of measures and thresholds, using a database along with any required preprocessing, sub sampling, and transformation of the database. There are five stages considered, namely, selection, preprocessing, transformation, data mining, and interpretation/evaluation as presented in Figure 1:

- **Selection:** This stage consists on creating a target data set, or on focusing in a subset

- of variables or data samples, on which discovery is to be performed;
- **Preprocessing:** This stage consists on the target data cleaning and preprocessing in order to obtain consistent data;
- **Transformation:** This stage consists on the transformation of the data using dimensionality reduction or transformation methods;
- **Data Mining:** This stage consists on the searching for patterns of interest in a particular representational form, depending on the DM objective (usually, prediction);
- **Interpretation/Evaluation:** This stage consists on the interpretation and evaluation of the mined patterns.” (Azevedo & Santos, 2008, p. 183)

The KDD process is preceded by the development of an understanding of the application domain, the relevant prior knowledge, and the goals of the end-user. It must be continued by knowledge

consolidation, incorporating this knowledge into the system. The KDD process is interactive and iterative, involving numerous steps with many decisions being made by the user (Brachman, J., & Anand, 1996).

As of the foundations of KDD and DM, several applications were developed in many diversified fields. The growth of the attention paid to the area emerged from the rising of big databases in an increasing and differentiated number of organizations. Nevertheless, there is the risk of wasting all the value and wealthy of information contained in these databases, unless the adequate techniques are used to extract useful knowledge (Chen, Han, & Yu, 1996) (Fayyad U. M., 1997) (Simoudis, 1996). The application of DM techniques with success can be found in a wide and diversified range of applications, for instance, bioinformatics, ecology and sustainability, finance, industry, marketing, scientific research, telecommunications, and other applications (Azevedo & Santos, 2011).

Figure 1. The KDD process

DATA MINING TASKS, METHODS/ALGORITHMS, AND MODELS/PATTERNS

Prediction and description were identified as the two “high-level” primary goals of DM (Fayyad, Piatetski-Shapiro, & Smyth, 1996). “Prediction involves using some variables or fields in the database to predict unknown or future values of other variables of interest. Description focuses on finding human-interpretable patterns on finding the data.” (Fayyad, Piatetski-Shapiro, & Smyth, 1996, p. 12)

To achieve these goals some DM tasks were used and its description can be found in the literature. Some of the most common DM tasks are classification, prediction, clustering, association, and summarization:

- Classification consists in finding a function that associates an instance of the independent variables to a specific pre-defined value of the target variable, named as class. The target variable should be of nominal type;
- Prediction consists in finding a function that associates an instance of the independent variables to some numerical value of a real-valued target variable, in order to predict future unknown values for that target variable;
- Clustering allows the identification of homogeneous groups containing several elements which have high similarity with all the other elements of the same group, and that have low similarity to all the elements of the other groups;
- Association consists in finding a model that describes significant dependencies between variables, that is to say, identifying facts that can be directly or indirectly associated;
- Summarization uses methods to discover a compact description for data, in order to find a better description of the data, thus improving its understanding.

In the literature, a significant number of DM methods/algorithms have been developed to accomplish each task, and different kinds of DM models/patterns can be obtained. Classification methods include decision trees, classification rules, neural networks, support vector machines, Bayesian data analysis, Bayesian networks, and k-nearest neighbor. Prediction methods include linear regression, nonlinear regression, neural networks, decision trees, and k-nearest neighbor. Clustering methods include partitioning, hierarchical and model-based methods. Association is accomplished with association rules. Summarization methods include EDA (Exploratory Data Analysis) and OLAP (On-Line Analytical Processing).

An outline of this DM tasks, methods/algorithms, models/patterns, and guidance is presented in Table 1.

There are different forms of evaluating models’ interestingness in each case, such as cross-validation, bootstrapping, bagging and boosting, estimating confidence intervals, or ROC curves. There are also a large variety of alternatives to provide guidance, including accuracy and error measures. We will not discuss in more detail each one of these issues, since we consider it is outside the scope of this text. Several textbooks can be found that cover these topics in more detail, e.g. (Han & Kamber, 2012) (Hand, Mannila, & Smyth, 2001) (Larose, 2014) (Myatt, 2014) (Witten & Frank, 2011) (Ye, 2003).

The emergence of more complex types of data led to the development of new methods and models to cope with the new task of mining complex data. As examples, we can point out text mining (do Prado & Ferneda, 2008), web mining (content, structure, and usage) (Markov & Larose, 2007), spatial data mining (Nlenanya, 2009), graph mining (Zhang, Hu, Xia, Zhou, & Achananuparp, 2008), mining time-series data (Liabotis, Theodoulidis, & Saraaee, 2006), among others. In (Kumar, 2011) some trends and new domains are explored.

Table 1. Outline of DM tasks, methods/algorithms, models/patterns, and guidance

DM Tasks	Methods/Algorithms	Models/Patterns	Guidance
Classification	Decision trees (ID3, C4.5, C5, CART, ...)	Tree	Information Gain/Gini Index
	Classification rules (PRISM, RIPPER, ...)	Rules	Accuracy and Coverage
	Neural Networks (multilayer perceptron, back propagation, kohonen networks)	Neural Network	Error
	Support Vector Machines	Maximum margin hyperplane	Error
	Bayesian data analysis	Probability distribution	Conditional Probability
	Bayesian networks (K2, TAN)	Directed acyclic graph	Conditional Probability
	k-nearest neighbor	Pattern space	Distance function
Prediction	Linear regression	Linear function	Error
	Nonlinear regression	Nonlinear function	Error
	Neural Networks (multilayer perceptron, back propagation, kohonen networks)	Neural Network	Error
	Decision trees (ID3, C4.5, CART, ...)	Tree	Information Gain Gini Index
	k-nearest neighbor	Pattern space	Distance function
Clustering	Partitioning (k-means, k-medoids, ...)	Diagram	Measure of dissimilarity
	Hierarchical (BIRCH, ROCK, Chameleon)	Diagram	Measure of dissimilarity
	Model-based (EM, Kohonen networks)	Diagram	Measure of dissimilarity
Association	Association rules (Apriori, GRI, FP-growth)	Rules	Support and Confidence
Summarization	EDA	Tables, Charts	-----
	OLAP	OLAP cubes	-----

KDD, SEMMA, AND CRISP-DM

The acronym SEMMA stands for Sample, Explore, Modify, Model, Assess, and refers to the process of conducting a DM project. The SAS Institute considers a cycle with 5 stages for the process, which are, sample, explore, modify, model, and assess. SEMMA offers an easy to understand process, allowing an organized and adequate development and maintenance of DM projects. It thus confers a structure for his conception, creation and evolution, helping to present solutions to business problems as well as to find the DM business goals (Santos & Azevedo, 2005).

CRISP-DM stands for CROss-Industry Standard Process for Data Mining. It consists on a cycle that comprises six phases, which are business understanding, data understanding, data preparation, modeling, evaluation, and deployment. CRISP-DM is extremely complete and documented. All its stages are duly organized, structured and defined, allowing a project to be easily understood or revised (Chapman, et al., 2000).

A comparative study of KDD, SEMMA, and CRISP-DM is made in (Azevedo & Santos, 2008). The summary of the correspondence between the three is presented in Table 2.

Table 2. Summary of the correspondences between KDD, SEMMA and CRISP-DM

KDD	SEMMA	CRISP-DM
Pre KDD	-----	Business understanding
Selection	Sample	Data Understanding
Pre processing	Explore	
Transformation	Modify	Data preparation
Data mining	Model	Modeling
Interpretation/ Evaluation	Assessment	Evaluation
Post KDD	-----	Deployment

Azevedo & Santos, 2008, p. 185.

STANDARDS FOR DATA MINING

Some efforts are being made seeking the establishment of standards in the DM area, both by academics, and by people in the industry field.

Some of the efforts in the industrial field concern the definition of processes/methodologies that can guide the implementation of DM applications, for instance, SEMMA and CRISP-DM. Other efforts in the industrial field focus on the development of software suites for implementing some selected DM algorithms. Over the past few years several DM suites have been developed (KD-Nuggets, 2015). These suites deliver user-friendly environments that allow users to apply DM freely and easily. There are other efforts being made that intend to develop standards that will allow model representation to be platform independent. These models mainly seek portability among models obtained in different tools, and some of them are included in most of the Business Intelligence (BI) tools in the market (Azevedo & Santos, 2011).

Above all the academic efforts towards a theory for DM and KDD follow closely the theory developed by Codd for the Relational Model. A promising research line is that of Inductive Databases, as presented by (De Raedt, 2003), (Imielinski & Mannila, 1996), and (Dzeroski, 2007). According to the Inductive Databases framework, data and DM models are stored on the same database and

can be queried at the same level. The inductive query language is a fundamental issue to consider in the research. Based on this framework, some theoretical research and prototypes have been developed, as well as some research about DM Languages, such as QMBE (Azevedo & Santos, 2012) (Azevedo & Santos, 2013), DMQL (Han, Fu, Wang, Koperski, & Zaiane, 1996), MINERULE (Meo, Psaila, & Ceri, 1998), MSQL (Imielinski & Virmani, 1999), SINBAD (Kramer, et al., 2006), SPQL (Bonchi, Giannotti, Lucchesse, Orlando, & Trasarti, 2007), KDDML (Romei, Ruggieri, & Turini, 2006), XDM (Meo & Psaila, 2006), and RDM (De Raedt, 2002). Some of these efforts contribute to the integration of DM in BI systems. The dissemination of DM tools is increasing in BI as well as the acknowledgment of the relevance of its usage in enterprise BI systems.

FUTURE RESEARCH DIRECTIONS

Despite it can be considered as an established field, many open research questions still remains and many appear daily in the DM field. Examining the primary conferences and journals in the DM field, it can be concluded that the main issues for research are related to improving data preparation for DM, to developing better algorithms and methods for specific problems and applications, and to measuring the utility of the obtained models. But the range of the problems and applications rises as time goes by.

One research line, focus on the use of DM in the realm of unstructured data, such as text, the web, audio, videos, or images, among other. Also, the so called “big data” gains momentum as time goes by. Those topics are increasing in importance, and the development of more research in the area is very important. These new types of “data”, present research challenges along all the KDD process, from the data preparation to the interpretation of the obtained data mining models.

Another research line concerns the definition of standards for DM. This is a very dynamic line

of research. The main goal from the academic point of view consists in defining a DM system similar to the Database Management Systems (DBMS) defined by Codd for the relational model for databases. The DBMS allow the user to easily access and manipulate data stored in databases and a similar system is desired for DM in order to allow the user to also access and manipulate de DM models. Some promising efforts were done, but there are some important drawbacks that need to be overcome. Just to present one example, the types of models that the languages, referred in the end of the previous section, can support are almost limited to rules.

This research line is strongly connected to a novel research line: DM integration with BI systems. This is a promising research line whose main goal is to allow final business users to really access and be able to manipulate DM models in order to completely extract their inner value.

CONCLUSION

This article presents a simple but comprehensive examination of the main issues related to DM. It presents the roots of the field. It also presents a very useful summarization of the main DM tasks and the respective methods/algorithms and models/patterns. The parallelism of KDD, SEMMA, and CRISP-DM is also very useful to the field. A usually not approached theme in DM texts is hereby included: standards for DM. This is a very important topic that, in my opinion, will represent the main core of research in the DM field hereafter.

Despite sometimes the DM field is considered as an established field with little remaining for research, this article presents several lines of research containing a good deal of open research issues waiting to be explored.

KEY TERMS AND DEFINITIONS

Data Mining Algorithms: A sequence of steps that allows obtaining a data mining model.

Data Mining Language: Allows users to directly manipulate data and models at the same level.

Data Mining Models: Are obtained from the application of data mining methods/algorithms. There simple models, such as rules or trees, and more complex models, such as neural networks.

Data Mining Task: What is pretended to achieve when applying Data Mining, for instance classify.

Data Mining: One of the phases of the KDD process and concerns, mainly, to the means by which the patterns/models are extracted and enumerated from data. Many times is identified with the complete KDD process.

Inductive Database: Data and data mining models are stored at the same level on the same database and can be queried.

Standard: That obeys to settled parameters.

Data Mining and the KDD Process

D**Ana Funes***Universidad Nacional de San Luis, Argentina***Aristides Dasso***Universidad Nacional de San Luis, Argentina*

INTRODUCTION

The constant search for diseases causes, the improvement of automatic diagnoses methods, financial data analytics and market tendencies, among others, are only some of the innumerable applications where analysis and discovery of new patterns have fuelled the research and development of new methods, all related to machine intelligence, knowledge extraction from what is now being called ‘big data’, Knowledge Discovery in Databases or KDD, and Data Mining.

The development of these fields has benefited from the existence of large volumes of data proceeding from the most diverse sources and domains, e.g. entrepreneurial historical data bases, medical data bases, biological data bases, astronomical data, etc. KDD process and methods of Data Mining allows for the discovery of knowledge in data that is hidden to humans, particularly when data volumes are large or even extremely large, presenting the knowledge extracted under different ways: rules, equations, decision trees, etc., and helping to answer questions such as *what are the groups from a population of individuals with common characteristics?*, *is this client reliable?*, *is this e-mail spam?*, etc.

Answers to these questions, as well as to many others, are different from the traditional answers obtained from queries in On Line Transactions Processing (OLTP), where the information is not hidden neither is discovered, but it is presented summarized in an agreed format or report. They also differ from information proceeding from Online Analytical Processing (OLAP), which can

be presented in different perspectives or aggregated in different ways and not just summarized as in OLTP, and that can even escalate to the use of big data, where OLTP fails. However, both of these methods are not capable of discover new knowledge neither producing new patterns and rules as is the case with the KDD process.

In this chapter, an overview of the KDD process and all its stages is given, including Data Selection, Cleaning, etc., with especial attention to the phase of Data Mining, its tasks and methods, as well as its relation to other areas such as Machine Learning, Inductive Logic Programming (ILP), Statistics, etc. A discussion of a possible classification of Data Mining methods is also given as well as an overview of future challenges in the field.

BACKGROUND

There exists some confusion in the use of the terms of *Knowledge Discovery in Databases* or KDD and *Data Mining*. Frequently these terms are interchanged, using Data Mining as synonym of KDD. Although they are strongly related, it is important to clarify the differences between them.

Several definitions of Data Mining can be found in the literature. Witten and Frank (2000) refers to Data Mining as the process of extraction of previously-unknown, useful and understandable knowledge from big volumes of data, which can be in different formats and come from different sources. In a much more short way, Hernández-Orallo, Ferri and Ramírez-Quintana (2004) define Data Mining as the process of converting data

Figure 1. Data mining and its relationships with other fields

into knowledge. Sometimes Data Mining is also referred by many other names including *knowledge extraction*, *information discovery*, *information harvesting*, *data archeology*, and *data pattern processing* (Fayyad et al, 1996a).

The notion of Data Mining is not new. Since the 60s, other terms as *Data Fishing* or *Data Dredging* have been used by statisticians to refer to the idea of finding correlations in data without a previous hypothesis as underlying causality. However, it is not until the late 80s that Data Mining became a discipline of Computer Science and scientific community adopted the term. In fact, as Witten and Frank (2005) point out, *the first book on data mining appeared in 1991 (Piatetsky-Shapiro and Frawley, 1991)—a collection of papers presented at a workshop on knowledge discovery in databases in the late 1980s.*

Data Mining is a branch of Artificial Intelligence, closely related to Machine Learning, where Machine Learning provides the technical

basis for Data Mining (Witten and Frank, 2005). Data Mining deals with *inductive learning* in a practical and not theoretical way (as Machine Learning does), making use of tools provided by Machine Learning. It applies Machine Learning techniques as well as other statistical and algebraic techniques to find structural patterns hidden in data, with the main objective of describing data or making predictions from them.

Artificial Intelligence comprises not only Machine Learning but other disciplines such as *Robotics*, *Logic Programming* and *Inductive Logic Programming* (ILP), which is a field of Machine Learning and Data Mining. Figure 1 shows a schematic view of the relationships between Data Mining, Machine Learning, Artificial Intelligence and other associated disciplines.

As it can be seen in Figure 1, Data Mining adopts techniques and methods not only from Machine Learning —area with which is closely related— but also from Statistics.

According to Tom Mitchell (1997), Machine Learning provides techniques; some of which are used by Data Mining for the development of software that is able to improve with experience. However, a valid question is *how a computer can improve with experience?* One answer to this question could be *by learning*. But, then, a new question arises: *can a computer learn?* Technically, when talking about *learning*, the only objective way of answer to this question is by using some kind of metric that allows measuring the performance when achieving a given task, and then observing how much better the same task has been solved after learning. For example, a set of data with information about bank customers, who have received a loan from the bank and have been classified as reliable/no reliable according with their loan payment history, could be used for learning the concept *reliable*. Later, an indicator of how much this concept has been learnt by the computer could be taken by measuring its capacity for correctly classifying new customers.

Machine Learning focus on the study of inductive learning; this inductive process consists in searching patterns hidden in a given evidence; once a model has been learnt, it can be used in the future to make predictions over new evidence or to describe new instances.

Although computers cannot already learn as human beings do, there is an important number of algorithms that work properly to solve certain tasks, e.g. image recognition, sound recognition, clustering, classification, categorization, among others.

Many authors, e.g. Hernández et al. (2004), Fayyad et al. (1996a), place Data Mining as part of a larger process called Knowledge Discovery in Databases (usually referred by its acronym KDD). This process involves a number of sub processes such as data selection and integration, preprocessing, Data Mining, and evaluation and interpretation of results. Therefore, in this context, Data Mining is viewed as a sub-process within the overall KDD process, which is concerned with the discovery of knowledge hidden in databases.

According to Klossgen and Zytkow (1996), KDD applies the knowledge discovery process to databases. Perhaps the most accepted KDD definition is Fayyad et al.'s (1996b), who define KDD as *a non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data*, giving a broader and more general application domain for the knowledge extraction process.

DATA MINING: A PHASE IN KDD PROCESS

The KDD process is an iterative process that consists in the selection, cleaning and transformation of data coming not only from traditional databases but also from other heterogeneous sources, such as plain text, data warehouses, images, sound, etc., aimed to apply data mining algorithms to them in order to discover valid, novel, potentially useful, and understandable hidden patterns. Once patterns are obtained, they are interpreted and evaluated, going back if necessary to previous phases for a new iteration.

Figure 2. shows a graphical representation of the KDD process. Some authors decompose it in more phases; nevertheless, its activities are basically the same.

During the first phase (*Data Selection/Sampling*) of the KDD process, activities that have to do with data collection and integration take place. Frequently, data are collected from the most diverse sources (organizations, departments, databases, etc.); hence they do not share the same format and structure. In these cases, an activity of data integration is required. This has given place to the concept of *data warehouse*, a technology used by organizations to collect data from different sources for the purpose of analysis and decision making (e.g. evolution forecast, organizational analysis, and strategies' design).

Unlike databases, mainly used by applications based in traditional processing of data, known as OLTP (On-Line Transaction Processing), data

Figure 2. The KDD process

warehouses are operated by OLAP (On-Line Analytical Processing) tools. Data warehouses have a different data organization from databases, adopting a multidimensional data model.

Like OLAP, Data Mining techniques can make use of data from data warehouses, but as Hernández-Orallo et al. (2004) express, there is an important difference between OLAP and Data Mining: an OLAP tool allows to aggregate detailed information getting reports and views in real time, besides which, it permits to verify patterns and hypothesis suggested by the user, i.e. it is essentially a *deductive* process. On the contrary, Data Mining is an *inductive* process that uses data to infer patterns. Nevertheless, let us note that OLAP tools can also be used in the first stages of the KDD process for a better understanding of data.

A second phase of *Preprocessing/Cleaning and Transformation* is sometimes needed. During this stage, a *minable view* of the previously integrated data is created. A minable view is a subset of the integrated data, which will be the input to the data mining algorithms to be applied. A minable view eliminates unnecessary data, which are irrelevant for the data mining task. To that effect, activities such as creation of new attributes, selection of relevant attributes, attribute transformation and reduction in the number of observations to be considered take place. Sometimes, missing values and *outliers* (anomalous values) are also eliminated, especially when the algorithm used is sensible to their presence.

Once the minable view is ready, the *Data Mining* phase can proceed. In this phase, decisions about the method or technique (e.g. decision trees) to adopt for solving a task (e.g. classification) must be taken. In this phase the algorithms to be applied to the minable view (e.g. CART, C4.5) must be chosen. In the next section an overview of Data Mining's tasks, methods and algorithms is given.

The last phase of the KDD process, showed in the picture as *Evaluation and Interpretation* of patterns, is where the model learnt from data mining is evaluated, after which a new iteration begins starting from one of the previous stages whenever it is necessary.

Evaluation is a very important process since it involves determining which of the models among several alternatives is going to be kept for solving the problem at hand. Therefore, techniques to evaluate how well the different methods work to solve the problem and to compare them are mandatory.

Model evaluation techniques and measures depend on the kind of task to solve (descriptive/predictive). For example, in predictive tasks, such as classification, evaluation techniques split the evidence in sets for training and evaluation. This is done to guarantee that the model evaluation measure obtained from the test set is an independent measure, avoiding too optimistic estimations. For example, a typical evaluation measure for classification models is *error rate/accuracy*, defined as the proportion of incorrectly/correctly classified instances over the total number of instances.

The most simplistic evaluation technique for predictive task is *simple validation*, where the evidence is split in two sets, one for testing (*test set*) and the other for training (*training set*). However, there exist most sophisticated techniques such as *cross validation*, *n-fold cross validation*, useful when the evidence is scarce, or *bootstrapping* (Efron and Tibshirani, 1993) (Kohavi, 1995a).

In descriptive tasks, such as clustering and association rules, different measures are used. For example, *coverage* (or *support*) and *accuracy* (or *confidence*) are used for association rules.

LEARNING TASKS, METHODS AND ALGORITHMS IN DATA MINING

Data Mining Tasks

In Data Mining, as in many other disciplines, there exist families of problems. Each of these families, in Data Mining, is called *learning task* and it can be solved by means of diverse *methods* and *algorithms*. *Classification*, *regression*, *clustering*, *correlations* and *association rules* can be mentioned among the most important data mining tasks.

As a result of each task, according to the problem it solves, a prediction or a description is obtained, giving place to *predictive* and *descriptive tasks*. Predictive tasks, as its name indicates, estimate unknown or future values, while descriptive tasks search hidden patterns in data as a way of explaining or describing them.

One of the most common predictive tasks is *classification*, while correlations, association rules, functional dependencies and clustering are descriptive tasks.

A *classification task* consists in labeling each new instance with a tag (the *class*), from a set of possible classes. Classification predicts the class of an instance from the values of its attributes. For example, a model used to classify new messages as spam/no spam that previously have learned the concept of spam from old messages labeled as spam/no spam.

There are variations to classification like *categorization*, where an instance can be labeled with more than one class. Other variants to classification are *soft classification* and *probabilistic classification*. A soft classifier not only assigns a class but also an estimation of the degree of certainty. Probabilistic classification is a generalization of soft classification; here, for each instance, the classifier predicts a probability distribution for the set of possible classes, i.e. for each instance it predicts the probability of belonging to a class. Let us note that, when the number of classes is two, a probabilistic classifier is equivalent to a soft classifier.

Another descriptive task is *preference learning*, where a ranking is learnt. The learning process is carried out not from a set of instances as in classification but from a set of sequences of instances, where the order in a sequence represents the preference order of the instances in the sequence. For example, given a set of candidates for a job position, to get a preference order of the candidates based on their attribute's values and previous preference rankings from which to learn the new preference order.

Regression is also another important predictive task. In this case, a real value is predicted, i.e., a real function is learnt. An example of a regression task is the productivity estimation for a company based on past productivity values. When a real value is predicted for the future, this task is referred as *estimation*, and when the real value predicted is between two known values it is referred as *interpolation*.

On the other hand, *Correlations* are a descriptive task. They are useful to determine whether two numeric variables are correlated, i.e. whether they have a similar behavior. When there is a positive correlation, both variables increase and decrease at the same time; if the correlation is negative one decreases when the other increases. A correlation not only can be positive or negative but it also can be strong or weak or nonexistent. This task is used in data mining to determine redundant attributes or dependencies among them.

Association rules is also a descriptive task that, as correlations, finds existing relationships among categorical (non numerical) attributes. Given evidence from a set in $A_1 \times A_2 \times \dots \times A_n$, where A_i is the domain of an attribute, an association rule is defined as an implication, usually in the form

“if $A_i = a \wedge A_j = b \wedge \dots \wedge A_k = g$ then $A_r = u \wedge A_s = v \wedge \dots \wedge A_t = w$ ”

For example, from an analysis of purchase baskets the following rule could be inferred:

“if *baby_food* = YES then *diapers* = YES”

Functional dependencies are a variation of association rules, where only one attribute is determined from a subset of the remaining attributes. For example, a functional dependency could determine that a person is a homeowner from his/her age, income and marital status.

Finally, the descriptive task of *clustering* consists in partitioning a set of instances in natural groups called clusters. Originally, the central concept for clustering was the use of a numeric measure of similarity between the instances, creating clusters where the similarity among the members of a cluster is maximized and the similarity between the members of different clusters is minimized. A different approach to clustering is *conceptual clustering* proposed by Michalski (1980), which is not based in the notion of similarity but in the concept of *conceptual cohesion* (Michalski and Stepp, 1983a). In conceptual clustering, two individuals belong to the same cluster not because they are similar (according to a similarity measure or distance) but because they are part of a same concept or, in other words, they are described by a same concept. These two different views of clustering have given place to different approaches to this task: *similarity based clustering* and *conceptual clustering*.

The main application of clustering is in guessing that new instances that have been considered to be members of a cluster have similar behavior

or characteristics that the members of that cluster. For example, an on-line shop could make use of clustering to create groups of customers according to their purchase preferences, and then when a customer buys an article the system offers other articles based on the preferences of others customers in the same cluster.

Data Mining Methods and Algorithms

There is an important number of *learning methods* that support the previously described data mining tasks. For example, a classification task can be solved using different methods, e.g. neural networks or decision trees. At the same time, for each particular method different algorithms supporting it can be found. For example, there are several decision trees algorithms, such as ID3 (Quinlan, 1986) or its extension C4.5 (Quinlan, 1993). Many of them can be used to solve different tasks, e.g. *k*-nearest neighbor algorithm can be used for classification, regression and also for clustering.

In general, data mining methods can be placed into two large categories: *supervised* and *unsupervised* methods.

In supervised methods, models are learnt from examples, where there is a *teacher* or *supervisor* (expert) who defines the classes and provides examples for each class. These examples form a training set, which is used to build a model that allows predicting the class of new examples. Some supervised methods learn a function, i.e. the class are disjoint, while others learn a relationship, where classes can be overlapped. The first corresponds to the task of classification, while the second to categorization.

In unsupervised methods, learning is by observation and discovery. Here, the examples used for learning are not labeled with a class as in supervised methods but the methods must observe the examples and recognize patterns by themselves.

Both supervised and unsupervised methods adhere to one of two inductive learning approaches: symbolic learning or similarity-based learning. In

the next section a description of both approaches and an overview of their main methods are given.

Similarity-Based Methods

Similarity-base learning methods share the concept of *similarity* and other associated concepts like the notion of *distance* and neighborhood or proximity. Some kind of mechanism is needed to compare two objects and decide if they are similar. One way is by means of the use of a *similarity function*. A similarity function is a real function that given two objects returns a real value representing how similar these two objects are; it returns higher values while more similar the objects are. For example, a similarity function frequently used in Machine Learning is the *cosine similarity* measure between two vectors of real numbers; it is often used to compare documents.

The concept of *distance* or *metric* is associated to the notion of similarity, being the distance between two objects inversely proportional to the similarity between them. Even though a distance is a particular case of a similarity function, distances have certain properties that can be advantageously used by learning techniques.

Similarity-based methods support the idea that similar objects should behave in similar way. For example, given a similarity measure, a new

instance could be classified as belonging to the class that has the most similar instance; or in a clustering task, it could be placed it into the cluster that has the instances more similar to it.

A brief description of some well-known similarity-based supervised and unsupervised methods follows.

Supervised Similarity-Based Methods

Supervised Similarity-based methods learn from a set of labeled instances employing a similarity function or a distance to make their predictions. Examples of them are *k-Nearest Neighbors*, *Fisher's discriminant*, *Support Vector Machines*, *Learning Vector Quantization*, among others.

- **k-NN (k-Nearest Neighbors):** It is very simple and probably the best-known method. The idea behind *k-NN* is that the *k* nearest neighbors' majority class is assigned to each new instance.

The main problem is determining the optimum value for *k* (see Figure 3). Usually, $k = \sqrt{n}$ where *n* is the number of examples, is an option with a theoretical base.

Figure 3. Difference between the nearest neighbor classifications in function of the chosen value of *k*

Figure 4. Linear discriminants

Any data representation can be used provided that a suitable similarity function is found.

- **Support Vector Machines (SVM):** This method searches a linear discriminant that maximizes the distance to the examples in the border of a class.

The classifier simply computes the hyperplane that perfectly separates the classes and that maximize the distance from the examples in the class border to the frontier (see Figure 4).

SVM are very efficient, even for hundred of dimensions because the linear discriminant has only to see a few points, called the *support vectors*, avoiding all the points that are not close to the frontier.

When data cannot be lineally discriminated (see Figure 5), a *kernel* function can be applied, augmenting the number of dimensions in such a way that the data are separable.

A SVM model is a representation of the examples as points in a space, transformed in such a way that the examples are clearly separated. When a new example must be classified, this is transformed by the kernel function into the same space and classified according to the side of the hyperplane where the new example falls.

Figure 5. Set of examples not lineally separable

- **Learning Vector Quantization (LVQ):** The learned model is a collection of *prototypes*¹, where a new example is classified according to its proximity to those prototypes.

Given a training set with k classes, the algorithm randomly choose k prototypes, whose positions change until a given threshold is reached. This is an iterative process, where, in first place, an example from the training set is chosen and is labeled with the class of the closer prototype. Next, the class' prototype is recomputed. Depend-

ing on the prototype's and example's labels, the prototype position will change, making closer the new prototype to the example if both labels match or the opposite if they do not match. The process stops when the change in the prototypes positions is lesser than a give threshold or there are no more training examples.

Unsupervised Similarity-Based Methods

In unsupervised similarity-based learning, the evidence is presented as a set of unlabeled elements and the objective is to find a descriptive model from the evidence, in this case using a similarity function.

Learning of descriptive models can be carried out in different ways and by multiple tasks, e.g. *clustering*, *correlations* and *factorizations*, *association rules* and *functional dependencies*.

A possible classification of clustering methods is splitting them into *hierarchical clustering* and *partitioning clustering*. A well-known example of partitioning clustering is *k-means* algorithm; examples of hierarchical clustering are *agglomerative* and *divisive hierarchical clustering*.

Below a brief description of similarity-based clustering is given.

- Hierarchical Clustering Algorithms:** These algorithms produce nested series of partitions of the evidence using as criterion for splitting or merging the clusters a similarity function (generally a distance). A hierarchical algorithm produces as result a *dendrogram*, which represents the nested clusters. It also shows the similarity levels where a clustering changes to a new clustering (see Figure 6).

A dendrogram can be decomposed at different levels obtaining different data partitions. For example, in Figure 6, the dotted line cuts the hierarchy at the level corresponding to the clustering formed by the groups {A, B, C}, {D, E} and {F, G}.

- Partitioning Clustering Algorithms:** Unlike hierarchical clustering algorithms, which create a clustering hierarchy, this kind of algorithms produces only one partition of the evidence.

Figure 6. Example of dendrogram produced by a hierarchical clustering algorithm

One of the most known partitioning algorithms is *k-means*. It begins the process working with an initial random partition formed by k clusters and proceeds reassigning the examples to other clusters driven by the distance between the example and the clusters' *centroids*¹. Once all the examples have been reassigned, the clusters' centroids are recomputed. This process continues until a convergence criterion is reached (e.g. the examples cannot be reassigned or the quadratic error has reached a threshold after a given number of iterations). Although *k-means* is a popular algorithm because his implementation is simple and his complexity is $O(n)$, where n is the number of examples, it has the drawback of being sensible to the selection of the initial partition.

Model-Based Symbolic Methods

In similarity-based learning, the discovered models are determined by the similarity between the elements of the evidence. This fact makes the model hard to understand by the user. This is a weakness of similarity-based methods since in many cases to have a model that is comprehensible by a human is a must; for example, a learned model should provide an explanation or description of its recommendations when refusing a loan to a customer, that goes beyond saying that the customer is classified as unreliable.

In this section some supervised and unsupervised learning methods that produce comprehensible models from the evidence are described. This family of methods or techniques is known as *Symbolic Learning*.

Supervised Model-Based Symbolic Methods

Possibly, the most well-known supervised symbolic method is *decision trees*, where a predictive model in the shape of a tree structure is learnt from the evidence. Decision tree branches represent attributes conjunctions and its leaves correspond

Table 1. Evidence used to construct the decision tree shown in Figure 7

Outlook	Temperature	Humidity	Windy	Play
sunny	hot	high	FALSE	no
sunny	hot	high	TRUE	no
overcast	hot	high	FALSE	yes
rainy	mild	high	FALSE	yes
rainy	cool	normal	FALSE	yes
rainy	cool	normal	TRUE	no
overcast	cool	normal	TRUE	yes
sunny	mild	high	FALSE	no
sunny	cool	normal	FALSE	yes
rainy	mild	normal	FALSE	yes
sunny	mild	normal	TRUE	yes
overcast	mild	high	TRUE	yes
overcast	hot	normal	FALSE	yes
rainy	mild	high	TRUE	no

—in the case of *classification trees*—to a set of labels or classes, or to real values in the case of *regression trees*.

Figure 7 shows an example taken from (Witten and Frank, 2005) of a decision tree that has been induced from the data given in Table 1. This decision tree allows determine given a new instance whether to play a tennis match. The tree shows in its intermediate nodes the attributes outlook, humidity, and windy with their corresponding values on its arcs and the values yes/no of the class (play), on the leaves.

It can be noticed that although the attribute temperature appears in the data, this is not relevant to the decision (to play tennis or not), therefore temperature is not a node of the tree.

Whenever a new instance must be classified, the tree is traversed from the root according to the attribute values in the successive nodes until a leave is reached and the instance is classified with the value in the leave. For example, an instance with the attribute values outlook = sunny, temperature = cool, humidity = normal and windy = TRUE, will be classified with play = yes.

Figure 7. Decision tree to determine whether to play tennis

Unsupervised Symbolic Methods Based on the Model

In this section, two representative unsupervised symbolic methods, namely *Conceptual Clustering* (Michalski, 1979, 1980), (Michalski and Stepp, 1983a) and *Formal Concept Analysis* (FCA) (Ganter et al., 1999), which allow learning symbolic models from unlabeled examples, are described.

- Conceptual Clustering:** Classical distance-based unsupervised learning methods do not allow building conceptual descriptions of the discovered clusters. These methods leave to the user the problem of interpreting clusters. This is a limitation of distance-based methods since in some cases is useful not only to determine the groups but also to produce conceptual descriptions of them.

Michalski introduced, in 1980, the idea of grouping objects in categories that are described by concepts. The technique of conceptual clustering is composed of two main tasks: *structuring*, where the clusters are formed from a collection of objects and *characterization*, where concepts for each cluster of the structure are determined.

As it is explained in (Guerra-Sandón et al., 2012), the problem addressed by conceptual algorithms is of great practical usefulness. They are not limited to produce a list of objects that are in the same cluster and hence share similar characteristics or properties, but the intention of conceptual clustering is to provide additional information by giving the properties that the elements in each cluster satisfy.

Michalski was the precursor of these ideas and nowadays there are several algorithms for conceptual clustering. A conceptual clustering classification is given in (Guerra-Sandón et al., 2012); the authors classify conceptual clustering

algorithms into incremental and non incremental. Non incremental algorithms are those where all the training data are present at the same time, then the clustering is built from them; incremental algorithms process the examples one at the time, so each new example compels modifying the model obtained up to that moment. Incremental algorithms have been developed for those cases where the evidence is not completely given, i.e. is dynamic. Among the incremental algorithms, UNIMEM (Lebowitz, 1987), COBWEB (Fisher, 1987) and Galois (Carpineto and Romano, 1996) can be cited. Among the non incremental are CLUSTER/PAF (Michalski, 1979), CLUSTER/2 (Michalski and Stepp, 1983b), CLUSTER/S (Stepp and Michalski, 1986), WITT (Hanson and Bauer, 1989), ITERATE (Biswas et al., 1998), Conceptual K-Means (Ralambondrainy, 1995), LC Conceptual (Martínez-Trinidad, J. F. and Sánchez-Díaz, G., 2001) and HDCC (Funes et al., 2008), which is an hybrid between both paradigms (conceptual and distance-based).

Formal Concept Analysis. FCA allows identifying conceptual structures from data. These structures correspond to lattices of *formal concepts*, where each formal concept is a pair (*set of properties*, *set of examples*) and where the *set of properties* in the formal concept describes completely its *set of examples*. These lattices of formal concepts consist of a partial order relation defined as generalization relation between formal concepts. The main objective of FCA is offering compact descriptions of groups of data rather than a data clustering.

CONCLUSION

Our capacity for producing and storing data has notably increased during the last decades. This increment in the volume of data has gone up with our interest in exploring and analyzing

them. It is here that Data Mining has appeared as an emerging technology. Nowadays more and more enterprises, governmental, educational and all kind of organizations use Data Mining techniques for exploring, analyzing, understanding and applying the discovered knowledge extracted from big volumes of data. At the same time, an important number of both commercial and free tools have been developed; some of them oriented to particular domains, such as web mining and text mining tools, and others for general purpose mining.

FUTURE RESEARCH DIRECTIONS

Although data mining has achieved a big success and has given solution to many problems, there still exist some open research problems. In Qiang Yang and Xindong Wu (2006) ten challenging problems that give place to several research niches have been identified by consulting some of the most active researchers in data mining and machine learning. We enunciate them below as examples of possible fields of research:

- Developing a unifying theory of data mining.
- Scaling up for high dimensional data and high speed data streams.
- Mining sequence data and time series data.
- Mining complex knowledge from complex data.
- Data mining in a network setting.
- Distributed data mining and mining multi-agent data.
- Data mining for biological and environmental problems.
- Data Mining process-related problems.
- Security, privacy and data integrity.
- Dealing with non-static, unbalanced and cost-sensitive data.

KEY TERMS AND DEFINITIONS

Classification: Inductive task where a predictive model is learnt from objects labeled with a class and whereby it is possible to predict the class of new objects.

Clustering: Inductive task where a set of unlabeled objects is partitioned into groups (clusters) and where objects in a same cluster have similar characteristics, maximizing the similarity intra cluster and minimizing the similarity inter cluster.

Data Mining: The process of extraction of implicit, previously unknown, and potentially useful knowledge from data. It uses Machine Learning, statistical and visualization techniques to discover and present knowledge in a form that is easily comprehensible to humans. It is a phase in a bigger process: the Knowledge Discovery in Databases (KDD) process.

Inductive Learning: Induction is the inference of information from data and inductive learning is a model building process where the data are analyzed to find hidden patterns.

KDD Process: The KDD process is an iterative process that consists in the selection, cleaning and transformation of data coming not only from databases but also from other heterogeneous sources, such as plain text, data warehouses, images, sound, etc., aimed to apply to them data mining algorithms in order to discover valid, novel, potentially useful, and understandable hidden patterns.

Supervised Learning: Learning process of a predictive model from a set of objects, where a supervisor define classes and supply objects of each class. Once the model has been formulated it can be used to predict the class(es) of new objects.

Unsupervised Learning: Learning process of a descriptive model (patterns) by observation and discovery from a set of unlabeled objects.

ENDNOTE

- ¹ A set *prototype* is the set element that is in the center of the elements according to its metric space; i.e. it minimizes the sum of the distances to the other elements in the set. When this element does not belong to the set, it is called centroid.

INTRODUCTION

One of the most important organizational developments in recent years has been the significant growth of project work in different economic sectors and industries (Winter, Smith, Morris, & Cicmil, 2006). Thus, projects have become a key strategic working form. Further, it has been shown that all industries can benefit from project-based working (OPSR, 2003).

No longer just a sub-discipline of engineering, the management of projects -including program management and portfolio management- is now the dominant model in many organizations for strategy implementation, business transformation, continuous improvement and new product development (Winter et al., 2006). However, there is growing recognition that different types of projects require different approaches to their management (Müller & Turner, 2007). Furthermore, the increasing globalization of projects and project management adds intercultural challenges for project managers (Müller & Turner, 2004).

There is no doubt that management's configuration of projects affects the project's evolution. There are also factors like virtual teamwork and team building processes that are relevant to that evolution. Since effectiveness in managing projects depends on these factors, the authors

conducted this research to determine whether project performance varies according to project management and other factors. Thus, with a view to complementing other research to link project management to project success (Din, Abd-Hamid, & Bryde, 2011; Mir & Pinnington, 2014), this work considers factors such as virtual team configuration, team composition, knowledge competence, policy and strategy, project life monitoring and the level of detail implemented in managing projects that are undertaken in the learning process.

The data for this research was provided by an educational framework that was specifically designed to facilitate the learning experience of project management engineering students. The main purpose of this learning experience was to highlight how to move from simply learning content by rote to understanding, discussing and sharing (Alba-Elías, González-Marcos, & Ordieres-Meré, 2014). In this case, practitioners learned and applied by means of an experimental learning approach, a defined project management methodology that enables them to manage projects better.

Data mining and data analytics were used in this work to identify and understand the relationships between project performance and the analyzed factors. Data mining is widely applied in the educational area to predict students' performance

(Romero & Ventura, 2010; Shahiri, Husain, & Rashid, 2015). In the present research, we are much more interested in the project effectiveness that unexperienced project teams achieve, depending on specific factors. Thus, this study concentrates on using data mining for discovering patterns in project success, i.e., the performance of students as a team, instead of the performance of individual students.

The conclusions of our study can help higher education course designers, as well as teachers and students, by making clear the influence of smarter strategies in the learning process. In fact, the same benefits will help practitioners too, as they can improve their continuous learning procedures and adjust their own project management policies and strategies. Thus, the proposed research can be used as a specific decision tool of benefit in organizing projects according to specific parameters.

BACKGROUND

Project management is the application of knowledge, skills, tools and techniques to project activities to meet project requirements (PMI, 2008). The literature concerning project management includes many studies of critical success factors as can be seen in Wi & Jung (2010) or Alias, Zawawi, Yusof & Aris (2014). It is often agreed that project performance must achieve its objective and be aligned with criteria that the project stakeholders establish (Barclay, 2008). The usual metrics that are considered are cost, schedule and quality (ur Rehman Toor & Ogunlana, 2010). Indeed, the currently available standards are basically using these criteria in a process-oriented approach throughout the project's entire life cycle. Despite not being included in the three main strands of project management, sustainability has become a very important qualitative and quantitative step, particularly in the project's environmental aspects (Marcelino-Sádaba, González-Jaen, & Pérez-Ezcurdia, 2015). Thus, although sustain-

ability and project management traditionally have been tackled separately, the role of environmental management in projects is gaining more and more attention as an increasing number of publications in this field highlight (Marcelino-Sádaba et al., 2015; Økland, 2015).

Project performance has been of great interest to researchers and some authors have defined conceptual frameworks (Hewagamage & Hewagamage, 2011), as well as specific assessment models (González-Marcos, Alba-Elías, & Ordieres-Meré, 2016; Rehman, Usmani, & Al-Ahmari, 2012). Also, different studies have been conducted to investigate the impact of various factors on project performance. For instance, some studies for the Information and Communication Technology (ICT) projects, indicate that both users' knowledge of Information System and developers' knowledge of application domains have a significant impact on project performance (Byrd & Turner, 2001). In addition, insufficient personal knowledge about information system resources is a major reason for the failure of ICT projects (Tesch, Sobol, Klein, & Jiang, 2009).

However, despite the importance of technical factors, organizational and behavioral factors are considered in the literature to be the most relevant (Qureshi, Warraich, & Hijazi, 2009). Thus, all authors in the field recognize the relevance of continuous improvement and learning factors on project performance (Ojiako, Ashleigh, Chipulu, & Maguire, 2011). This applies not only to individuals, but also to the corporation. Therefore, elements such as lessons learned and project management maturity models are considered.

In this work an experiment that permits different layers of management (program and project management) to be reproduced was conducted. Thus, it was possible to study how managerial configuration of project management of virtual teams relates to project success. The main contribution of this work is the identification of quantitative relevance of described factors, as well as considering virtual teams as an additional driving factor.

DESCRIPTION OF THE ENVIRONMENT

Context

This experiment was designed to be a simulated environment in which challenge begins with a hypothetical company. It involves a new facility that the project owner intends to build in Spain to provide goods to the Spanish market. The owner is considering hiring a company to provide detailed engineering for its new plant. His owner expects to obtain the technical documentation that is necessary to authorize and build the facility. This includes both documents –specs, drawings, environmental impact assessment, etc.- and digital content like computer models and systems.

The requested companies that work as project teams in the program consist of students from three different universities - Universidad Politécnica de Madrid (UPM), Universidad de La Rioja (UR) and Universidad de León (ULE). Thus, different engineering students from different universities, different degrees and different levels of education were involved.

The experiment was conducted from September 2011 until May 2012. During this period all of the programs included different projects with different goals and durations. All of them were managed throughout with specifically designed information system that provided continuous monitoring of the progress during the period. This was the first time in all cases that practitioners were exposed to this methodology or project management theory and principles. Consequently, because of their previous knowledge, the participants can be expected to have been free of any bias.

The project enabled participants to assume various roles, ranging from project engineer (team members) to project and program manager (see Figure 1):

- Practitioners who were engaged as program managers (PGM) maintained their positions throughout the experiment. Thus,

they kept the scope for the whole program and they were responsible for the projects' evolution. Program managers were asked to produce an outline of the business case for projects that they wanted to manage in order to keep or increase the program's value. Close monitoring of project deliverables is expected, as the latter must be used as inputs for other projects or components of the final solution to be delivered to the customer.

- Project managers (PM) were responsible for defining and negotiating with the program managers the scope of the project, the deliverables to be produced by the project, etc. Project managers had the authority necessary for day-to-day management of the project.
- Team members (TM) were charged with the responsibility for engineering task development.
- Both program managers and project managers were able to negotiate and subcontract parts of its program or project to specialized companies. These companies consisted of one project manager (PMsc) and eight to ten team members (TMsc).

Teachers provided technical support in their feedback to different participants, although primarily to the program managers who assumed the role of owners for program outcomes. Thus, the instructor's team assumed the role of representatives for the aforementioned corporation. As an extension of their roles, teachers also worked as auditors to ensure that the basic technical rules for the experiment (e.g., procedures) were observed.

The methodology began with a proposal for five logical phases. These were similar to the five-phase project lifecycle that have been defined by the Project Management Institute (PMI) standard (PMI, 2008) for management of projects. They are Set Up, Planning, Execution, Control and Close. Theoretical classes emphasized the relevance of the methodology as a key aspect in managing

Figure 1. General structure of the experiment

Figure 2. Designed program and project phases (top) based on the five-phase project lifecycle defined by PMI standard (bottom)
PMI, 2008.

properly the project, and also in reviewing those actions and their significance in practical life. Furthermore, written procedures were provided to participants allowing them to review due steps at any time.

Experimental Design

In designing the experimental, it was decided to operate five independent programs that addressed the same goal, but different criteria for the selection of team members in both gender and prior education. Projects were defined within those programs according to the business case and the limited number of resources that were assigned to each program. At the beginning of the experiment, program managers were informed that ten to fifteen projects that had an average fifteen members per project would be sufficient in initially deciding how to split the scope for the program.

The level of desired scope definition and control was determined by program managers. The amount of detail in the project definition was negotiated between project managers and program managers (their customers) as a matter of their responsibility. Then, the project managers selected their own management level of detail that they would provide to answer their customers' requirements and to be able to manage the projects. This behavior is more or less the same as what we can find in real situations. No additional managerial orientations or constraints were provided at the beginning of the experiment. Instead, it was decided to restrict feedback to mistakes that became apparent in the actions that were undertaken. Thus, it was possible to identify specific statistically significant evidence of structural behavior due to because of specific design factors. By structural behavior, the authors meant parameters related to project management. These include intensity of project control derived from evidence, level of detail in planning the work, individualization of work at task level or degree of knowledge shared among project team members, among others. Relationships between this structural behavior and

classical project monitoring parameters (time, effort and quality) was also studied.

The main design factors that were considered at the program level were:

- **Previous Work Experience:** Programs 1 and 2 were assigned program managers who had previous functional working experience, although none had experience in projects or project management.
- **Gender Factor:** The participants in programs 1 and 4 were women and the participants in program 2 were men. The other programs contained both men and women.
- **Cultural Factors:** Programs 3 and 4 included a mixture of members of various nationalities. The members of other groups belonged to the same country or had a similar cultural behavior. In this work, term culture is used as a term for nations, since our mental programming is at least partly a product of our national background.

Information System

The experiment used an information system that collects real-time information about low level actions made during the project on the Project Management Office software. Also, it enables the creation of periodic reports to better identify mistakes or inappropriate behaviors. Finally, more than three hundred different variables were collected during the project's life. This amount of information provided a global view of the program itself, as well as a view at the project level.

The authors have selected some open-source tools that are oriented to web project management applications, as well as other tools that provide database capabilities. They also have developed their own tools to produce automated auditing reports in order to have continuous monitoring by team member, etc. The system uses most of the information gathered for automatically providing feedback to students. More details of the designed web-based support system can be found

in González-Marcos, Alba- Elías, & Ordieres-Meré (2013).

In this way, teachers can monitor more objectively and efficiently, as well as evaluate practitioners continuously throughout the whole experiment. Eventually, at the end of the experiment, a final assessment, which is similar to a post-mortem analysis, is prepared that considers all of the activity reports that were recorded.

RESEARCH DEVELOPMENT

As previously indicated, this experiment was created to study potential sensitivity of project configuration factors, such as origin of project members (local/virtual), gender and national cultural considerations and structural behavior of project performance.

In this study, project effectiveness was measured as the average quality over the time required in producing its goals in comparison to the initial estimate for that project. Since projects are intended to produce some deliverables at an expected quality by using a defined set of resources in a period of time, the defined measure was considered as a coherent metric of effectiveness.

Policies and strategies decided at project management level can also influence project performance. Since the information system collects detailed information about the process itself, the following factors are analyzed: workpackage level at the Work Breakdown Structure (WBS), level of detail in planning the work (number of tasks), average number of persons assigned per task (socialization) and details of control exercised.

In summary, this work attempted to determine the intensity of those different factors against effectiveness in project management. Furthermore, it looked for sufficient statistical evidence on additional factors, such as gender, team virtualization and previous experience.

More specifically, we have considered the following factors which are closely related to the ones previously identified:

- **Project Effectiveness (P_EFF):** Is the ratio of the performance obtained to what was planned. Effective performance is defined as the sum of perceived quality – on a Likert scale – of all deliverables produced over the amount of effort spent to produce them.
- **Detailed Project Scope (DPS):** Has been defined as the number of workpackages in the project.
- **Detailed Work Plan (DW):** Has been defined as the number of planned tasks in the project. Both summary tasks and normal tasks are counted.
- **Collaborative Dimension of Work (CW):** Has been defined as the average number of members per defined project task.
- **Detail of Control Performed (DC):** Has been defined as the number of entries at project's blog, as it accounts for messages exchanged between the team asking for specific requests or actions related to their project.
- **Percentage of Virtualized Team (PVT):** Has been defined as the lower fraction of team members per University over the number of project team members.
- **Percentage of Multicultural Management (PMM):** Lower fraction of project management members that have a different nationality over the number of project management members.
- **Gender Management (GM):** Can vary between '1','2','3' as if the project management team can consist of only females, only males or a mixture of the sexes.
- **Owner's Cultural Influence (OCI):** Because the owner of a project is the program, it is possible that national culture may influence the projects in the program. It has been defined as the lower fraction of program managers with different nationality.
- **Owner's Gender Influence (OGI):** It is possible that gender approach to manage-

Table 1. Main factors observed after the programs ended

Program Name	Gender	Work Experience	Multicultural Team	Detailed Monitoring	Quality
1	1: F	Yes	0%	4	4
2	2: M	Yes	0%	5	3
3	3: X	No	50%	3	3
4	1: F	No	50%	2	2
5	3: X	No	0%	2	3

ment affects the development of projects in the program. OGI has been defined as the program's Gender Management.

- **Owner's Level of Control (OLC):** A rank between 1 (the lowest level of control) and 5 (the highest level of control), according to the strategy that has been adopted by the program managers.

Table 1 illustrates the main differences between programs. These include such aspects as members' gender, previous work experience, team's multiculturalism, detailed monitoring and final quality. The detailed monitoring values were obtained by a formal assessment of the WBS. A five point Likert-type scale that ranged from 1 to 5, in which 1 indicated very poor and 5 indicated very good, was used for the detailed monitoring and quality parameters.

In order to simplify the analysis, some ranges have been defined by parameter, like the Likert scale, to represent different situations as being very low/very poor, low/poor, high/good or very high/very good. This facilitates a better understanding of underlying dependences.

RESULTS AND DISCUSSION

After conducting the experiment, some basic information about its evolution is presented. First, the number of finally scheduled projects in each program was not the same. Table 2 illustrates how programs established different numbers of projects, according to differing ideas of scope control that was to be imposed on the projects. Since the total number of resources was almost constant, the effect was to produce lighter project teams. The number of project failures experienced during the development was also highlighted. They differ statistically by program, which suggests some intrinsic factors.

As a matter of general understanding of program relevance, the project effectiveness factor (P_EFF) by program was studied (Figure 3). To this end, it makes sense to discuss the outlier that was observed in program 4, where the effectiveness was higher than one. The reason for this is that the project team accomplished the work with good quality in much less times than initially estimated.

In order to assess the program's impact, formal equivalence tests have been conducted. In

Table 2. Factors identified at program level

Factor	Prg 1	Prg 2	Prg 3	Prg 4	Prg 5
Number of projects	14	18	11	14	11
Number of failed projects	1	5	8	9	1
Averaged number of PM	3.2	3.26	3.25	3.1	3.5
Averaged number of TM	11.5	9.16	11.18	9.6	11.27
Averaged virtualization	26%	27.2%	16.5%	26.6%	42%

Figure 3. General performance of projects by program

equivalence studies, if the evidence does not sufficiently favor equivalence, nonequivalence cannot be ruled out. Thus, one-way ANOVA shows that null hypothesis can be rejected. This means that there are differences between programs according to the F-test (see Table 3).

By using the well-known Tukey's "Honest Significant Difference" method, program pairs 1–3, 1–4, 2–3, 2–4, 2–5, 3–5 and 4–5 exhibited strong differences that enabled us to emphasize how relevant the management style of a program had become for the projects that belonged to it.

Another relevant aspect to discuss is which of the different configuration factors can explain project effectiveness and why this could happen. To examine this, the authors established a five point Likert scale of project effectiveness. In this case, 1 indicated very low performance and 5 indicated

very high performance. Then, a classification tree was constructed (see Figure 4).

It is quite surprising how cultural factors (*OCI*) are becoming recognized as driving factors for program managers. It seems that program managers who belong to the same country or have similar cultural behavior provide better support. The underlying reason for this is not fully clear and additional research will be required. However, it appears to be related to how different program managers do their work according to their own standards and cultural patterns. These differences are perceived in the projects and deliver confusing messages about motivation and engagement.

In addition, it is clear that teams that do not pay enough attention to actively monitoring the project's progress ($DC < 274$ entries) evolve into

Table 3. Results of the ANOVA test of program relevance

	Df	Sum Sq	Mean Sq	F Value	Pr(>F)
Prg	4	1.64	0.41	4.14	0.0049
Residuals	63	6.26	0.10		

Figure 4. Relationship between project effectiveness and configuration factors

very low performing project teams. Similarly, a low level of scope definition ($DPS < 3$ workpackages) is recognized to be a driving force for a very low performing projects. The explanation is that a low scope detail leads to bigger project components for which defining the work to do and estimating the time required and cost is more difficult.

It is also worthwhile mentioning the impact of virtualized teams (PVT) on project effectiveness. The main reason is that teams' virtualization means more diverse skills (different behavior, ways of thinking, backgrounds, etc.) and, with careful management, teams become more productive.

For less virtualized teams (PVT) and mixed program management teams (OGI), it is important to mention how giving additional effort to managing the project gets recognition ($DW > 25$ tasks imply high performance).

SOLUTIONS AND RECOMMENDATIONS

The experiments were performed using a convenient sample of projects with a repeatability factor of five in order to consider diversity in them. They were designed to be developed without any

previous work experience at project level and considering it as a factor for programs. It was possible to experience slight variations if previous experiments become accepted at project level and this need to be investigated in the future.

On the other hand, despite the automatic system to collect evidence used in this experiment, it is always recommended that there be specific post-mortem analyses. Thus, it will be possible to identify the main reasons for specific behaviors and to discuss the relevance of introducing additional sensors to identify them for future projects.

FUTURE RESEARCH DIRECTIONS

Since individual skills could impact the team's morale and, therefore, the project effectiveness, future work will focus on measuring the evolution of individual competences during the experiment. In such work, the International Project Management Association (IPMA) competence model (IPMA, 2006) will be used as the reference for competence consideration.

Once individual competences have been measured, the authors intend to assess their impact on project effectiveness by using data mining.

CONCLUSION

The authors have designed and implemented an integrated platform that enables the monitoring of project activities on an individual basis. This infrastructure was used to run an experiment that was focused on analyzing the impact of various factors on project effectiveness. Thus, several guidelines can be derived that can help practitioners and course designers to improve the outcomes.

First, the significance of establishing program managers' teams based on similar cultural views becomes clear, as they will become the sponsors of projects being developed in those programs.

Also, it would be worthwhile to promote any kind of tool that encourages the sharing of infor-

mation about common mistakes to avoid and good managerial practices. It was made clear during this experiment that practitioners effectively exchange such kind of applied knowledge. Thus, it becomes easily disseminated throughout the organization. This must be accomplished by the work of highly motivated auditors, who play an important role in the early identification of mistakes and can make them visible for subsequent correction.

It also can be important to get teams virtualized as this allows participants to enrich their learning experience. Though exposure to different ways of thinking and the need to adopt additional management attitudes, they could increase the projects' effectiveness.

It is also relevant to emphasize the improvement is obtained when effective collaborative teams are organized. This is a project management strategy that must be emphasized to participants, not only from a theoretical point of view, but also on the basis of empirical evidence of the improvements achieved.

ACKNOWLEDGMENT

The authors wish to recognize the support of the Spanish "Ministerio de Educación" through its research funding program, as part of this work was supported by grants "EA-2010-0001" and "EDU2012-31080". The authors also appreciate the support of the "Vicerrectorado de Profesorado, Planificación e Innovación Docente" of the University of La Rioja through the "Dirección Académica de Formación e Innovación Docente" with its grant, APIDUR 2015.

KEY TERMS AND DEFINITIONS

Culture: The collective programming of the mind that distinguishes the members of one group or category of people from others.

Educational Data Mining: Techniques, tools, and research designed for automatically extracting meaning from large repositories of data generated by or related to people’s learning activities in educational settings.

Program: A group of related projects and other activities aligned with an organizational strategy or major goals, which are managed in a coordinated way to obtain benefits not available from managing them individually.

Project: A temporary endeavor consisting of coordinated and controlled activities with start and finish dates, undertaken to achieve an objective, i.e., to create a unique product, service, or result.

Scope: The sum of the products, services, and results with the specified features and functions to be provided as a project.

Virtual Team: A set of individuals who work across time, space and organizational boundaries and support the project manager in performing the work of the project to achieve its objectives.

Work Breakdown Structure (WBS): A hierarchical decomposition of the total scope of work to be carried out by the project team to accomplish the project objectives and create the required deliverables.

Workpackage: Unit of work or job defined at the lowest level of the work breakdown structure for which cost and duration can be estimated and managed.

Database Techniques for New Hardware

D**Xiongpai Qin***Renmin University of China, China***Yueguo Chen***Renmin University of China, China*

INTRODUCTION

In the last decade, computer hardware progresses with leaps and bounds. The advancements of hardware include: widely application of multi-core CPUs, using of GPUs in data intensive tasks, bigger and bigger main memory capacity, maturity and production use of non-volatile memory etc.

Database systems immediately benefit from faster CPU/GPU and bigger memory, and run faster. However, there are some pitfalls. For example, database systems running on multi-core processors may suffer from cache conflicts when the number of concurrently executing DB processes increases. To fully exploit advantages of new hardware to improve the performance of database systems, database software should be more or less revised (Ailamaki, 2004).

This chapter introduces some efforts of database research community in this aspect. And the following section gives a brief introduction to some new hardware technologies that database systems could utilized.

BACKGROUND

Multi-Core CPU

Improving the performance of CPU through increasing its clock frequency becomes more and more difficult. Researchers and engineers bring forth multi-core technology. In a typical multi-core CPU, 2, 4, 8 or more cores are integrated on one chip. Putting several cores on one die allows for

higher communication speeds between the cores, which will benefit many computing tasks.

The cores have their own private caches (Level 1 Cache, or L1 Cache), and share some larger but slower caches (L2 Cache). They access the shared main memory for parallel data processing. Database systems are basically multi-threaded, and they can benefit from multi-core CPUs without any modification. However, to fully utilize the cores to boost database performance, there is much work to do.

GPU for General Tasks

GPU is traditionally used to accelerate the specific task of graphic rendering. GPU vendors have integrated many computing units in a single die, and optimized the bandwidth to process large volume of graphic data. The highly parallelism of GPUs is exploited to speed up data intensive tasks as well, and GPU becomes GPGPU (General Purpose GPU).

Since GPU is designed primarily for graphic processing tasks instead of general tasks, the architecture of a GPU is rather different from CPU. It has its own unique thread hierarchy and memory hierarchy, which should be taken into account when using GPU for data processing tasks.

Bigger Memory

The price of memory is going down, now people can install more memory in a single server. It is rather common for a single server to possess a memory capacity as large as hundreds of giga-

bytes, or even up to terabytes. For moderate-size applications, it is possible to load the whole dataset into memory for fast access.

Non-Uniform Memory Access

Non-Uniform Memory Access (NUMA) machine is becoming more and more common. The NUMA architecture consists of a small number of processors, each having its own memory and I/O channels. Each group of CPUs is called a ‘node’. Memory that is local to a node is called local or near memory, while memory outside of a node is called foreign or far memory (Golding, 2010). Accessing foreign memory is much slower than accessing local memory. NUMA architecture requires changes of memory management.

Non-Volatile Memory, Solid State Disks, and Changes of the Memory Hierarchy

Non-volatile memory (NVRAM) is a type of computer memory that can keep the information even after the power is turned off. There are several flavors of NVRAM, including flash memory, and phase change memory (PCM) etc.

Flash memory devices use two different logical technologies, i.e. NOR and NAND, to map data. NOR flash reads and writes data in specific memory locations. It provides high-speed random access and it can retrieve a single byte. NAND flash reads and writes sequentially at high speed in small blocks called pages. In general, reading data from flash memory is much faster than writing data into it.

Phase-change memory (PCM) is a form of computer RAM (Random Access Memory). It stores data by altering the state of the matter from which the device is made. PCM is byte addressable. It incurs very low power consumption. And it has the potential to provide inexpensive, high speed, and high volume non-volatile storage.

A solid state disk (SSD) uses integrated circuit as memory to store data permanently. SSDs have

no moving parts, they are more resistant to physical shocks, run silently, have lower access time and latency, and consume much less power. SSD is usually made of flash memory. With the price of flash memory continues to decline, the price of SSDs is also declining over time.

With advent of non-volatile memory and SSDs, traditional memory hierarchy has been enriched with new intermediate levels. Recent and hot data could be kept in high speed memory levels, which is near to CPU, and historical and cold data could be migrated to low speed memory or disks.

MAIN FOCUS OF THE ARTICLE

Database researchers have devised many new techniques to utilize characteristics of above introduced hardware to improve performance of database systems. We classify these techniques into several categories, i.e. storage, index, query processing, transaction processing & concurrency control, and recovery.

Storage and Compression and Migration

Data Layouts

Traditional database systems are designed around disks. Data is primarily stored in disks, and it is loaded into memory buffer for later process. Now the memory capacity is so big, and it could be used as primary store of data. The whole dataset or most data can be kept in memory for faster access. Outdated or unused data is occasionally evicted to disks to make room for data that will be accessed soon (Zhang, Chen, Ooi, Wong, Wu, & Xia, 2015). The design principle is called “anti-caching”. In these scenarios, the optimization focus has shifted to how to efficiently exchange data between main memory and CPU cache for faster processing.

For a relational table, data could be stored in three styles of layouts: row-wise, columnar, and

PAX. It is straightforward to store rows of a table row by row in a data page. The layout is called N-ary Storage Model (NSM) (Gray, & Reuter, 1992). Traditional database systems for OLTP (online transaction processing) applications usually adopt a row-wise storage layout, since transactions on these systems access only a small number of rows. However, NSM model exhibits low cache utilization on multi-core platforms (Ailamaki, DeWitt, Hill, & Skounakis, 2001).

Columnar data layout, on the other hand, partitions a table into columns, and each column is stored contiguously. Columnar databases have shown to perform more than an order of magnitude better than traditional row-wise database systems on analytical workloads, in which most queries scan large volume of data, and touch only several columns (Abadi, Madden, & Hachem, 2008). Various compression techniques can be applied to reduce the space consumption. Columnar stores are actually successor of decomposed storage model (DSM) (Abadi, Boncz, & Harizopoulos, 2009).

Ailamaki et al. (Ailamaki, DeWitt, Hill, & Skounakis, 2001) have proposed a new data organization model called PAX (Partition Attributes Across). In PAX, a table is firstly horizontally partitioned into pages. In each page, all values of each attribute are grouped together. The PAX data layout greatly improves cache performance. According to their experimental results, PAX save at least 75% of stall time due to data cache accesses. Range select queries and updates on memory resident table execute 17-25% faster, and TPC-H queries execute 11-48% faster compared to NSM storage layout. PAX is highly scalable since the data is horizontally partitioned.

Row formats are ideal for OLTP workloads, which typically access only a small number of rows. Column formats are suited for analytics queries, which typically examine a small number of columns from a large number of rows. While PAX is suited for hybrid applications with OLTP and OLAP workloads.

Some researchers tried to combine read-optimized and write-optimized storage models

together to support hybrid workloads (OLTP and OLAP). In the work of (Kruger, Grund, Tinnefeld, Plattner, Zeier, & Faerber, 2010), a write-optimized buffer is used to maintain the delta data (recently inserted/updated data), in conjunction with the read-optimized main store, to support hybrid workloads.

Kissinger et.al. proposed an NUMA-aware in-memory storage engine named ERIS (Kissinger, Kiefer, Schlegel, Habich, Molka, & Lehner, 2014). ERIS uses an adaptive partitioning method to exploit the topology of the underlying NUMA platform. It reduces NUMA-related issues significantly. Experiments conducted on a system of 64 multiprocessors, 512 cores, and 8 TBs main memory and another smaller server demonstrated its superior performance over a NUMA-unaware index for different workloads.

Data Compression

Various compression techniques such as dictionary based encoding, bit vector encoding, run length encoding etc. (Krueger, Wust, Linkhorst, & Plattner, 2012) could be applied to memory resident data to reduce space consumption.

Data Migration in Memory Hierarchy

In many applications, data accesses have skewed patterns, where some records are hot (frequently accessed) but many others are cold (infrequently or never accessed). It will be economical to keep hot data in main memory and migrate cold data to low speed memories such as SSD.

In 2015, Sun proposed the *Sluice Gate Theory* (Sun, 2015) for data transferring among different levels of the memory hierarchy. In Sun's opinion, data transfer in a memory hierarchy is staged, and different stages have different capacities. Data is bumped and delayed at stage change (gate), and not all data goes to the next step. Data transferring in a memory hierarchy is something more like water transferring in sluice other than flowing in a river. The model has the potential to greatly improve

performance of data intensive computing when hardware and software are properly co-designed under the principle.

Eldawy et.al. (Eldawy, Levandoski, Larson, 2014) proposed the Siberia architecture, which migrates cold data to secondary storage and provides an interface to users to read and modify both hot and cold data, while minimizing number of accesses to cold storage. Records can be migrated between hot and cold stores while DBMS is still online. In main-memory optimized databases, appropriate cold data access rates incur an acceptable 7-14% throughput loss.

Index

When retrieving data from database, we can avoid full table scans when there are some indexes to located relevant data. New indexing techniques can be roughly classified into three categories, cache conscious indexes, cache oblivious indexes, and other index schemes such as those designed for non-volatile memory.

Cache conscious indexes are designed to reduce cache misses, based on parameters of memory hierarchy such as the number of memory levels, the block size of each level, and the relative R/W speed of each level. In contrast, cache oblivious indexes are designed to be independent of the parameters of memory hierarchy to achieve acceptable performance no matter what hardware platforms the database system is running on.

Cache Conscious Indexes

Rao and Ross proposed a cache conscious B+-tree called “Cache Sensitive B+-trees” (Rao, & Ross, 2000). The goal is to make B+-trees as cache conscious as CSS-trees (Cache Sensitive Search trees) without increasing the update cost too much. The tree stores all the child nodes of any given node contiguously, and keeps only the address of the first child in each node. The rest of the children can be located by adding an offset to that address. Since only one child pointer is stored

explicitly, the utilization of a cache line is higher. CSB+-trees support incremental updates in some way similar to B+-trees.

Dong and Xu presented a cache conscious R-tree variant (Dong, & Xu, 2007). Firstly, Quantized Bounding Spheres (QBSs) are introduced to approximate data points or bounding spheres. Then the advantages of QBSs and the Quantized Bounding Rectangles (QBRs) are incorporated into the cache conscious R tree (CSR+-tree). A new distance computation scheme is proposed to avoid the decompressing of QBSs or QBRs, which leads to significant run time reduction. The experiment results show that CSR+-tree consistently outperforms other representative indexes.

Faust et. al. (Faust, Schwalb, & Kruger, 2013) presented Paged Index, a sparse index tailored towards dictionary-encoded columns. By indexing the occurrence of values on a block level, the search scope for scan operations can be reduced drastically. They achieved up to two orders of magnitude of performance improvement for the column scan operations, paying only a little overhead for index maintenance and storage.

Binna et. al. (Binna, Pacher, Meindl, & Specht, 2014) proposed a cache conscious index structure DCB-tree for storing of short fixed size keys. They combined a hierarchical cache aligned node layout with delta encoding and pointer compression. Compared to other main-memory index structures, DCB-tree reduces the amount of memory required by 80% in the best case and by 30% in the worst case, while providing equal or better performance for large real world datasets.

Cache Oblivious Indexes

Bender et. al. proposed a cache oblivious B-tree (Bender, Demaine, & Farach-Colton, 2000). The first data structure permits optimal scans and searches from any node in the tree. The insertion and deletion costs for this data structure match the bound of $B = O((\log N)^2 (\log \log N)^4)$. The second data structure uses indirection and performs scans optimally. For this structure, insertions and dele-

tions match the bound of $B = O(\log N \log \log N)$. The third data structure also uses indirection, and insertions and deletions always match the B-tree bound.

Arge et. al. proposed a cache oblivious R-tree (Arge, Berg, & Haverkort, 2009). They created a cache oblivious data structure to store a set S , of N axis-aligned rectangles in the plane. The structure allows all rectangles in S , which intersect a query rectangle or a point, to be found efficiently. For any constant ϵ , a rectangle query can be answered using $O(\sqrt{T/B})$ memory transfers, and a point query can be answered using $O((N/B)^\epsilon)$ memory transfers, where T denotes the number of reported rectangles, and B denotes the block size of memory being transferred between any two levels of the memory hierarchy.

Lindstrom and Rajan (2014) proposed a general framework for generating cache oblivious layouts for binary search trees through recursively partitioning a tree into contiguous subtrees and prescribing an ordering amongst the subtrees. They also derived a new locality measure, i.e. the *Weighted Edge Product* to approximate the probability of cache misses at multiple levels. The *MIN WEP* layout for a complete binary search tree optimized by the *Weighted Edge Product* outperforms previous cache-oblivious layouts by around 20%.

Other Index Techniques

To speed up ad-hoc queries, Petraki et. al. (Petraki, Idreos, & Manegold, 2015) proposed a holistic indexing scheme. It makes use of available CPU resources and continuously adapts the index to workload changes, without human intervention. Runtime adaption does not affect the running queries negatively. In the meanwhile, the refinement of the physical design based on the changing workloads brings substantial performance improvements.

PCM's long write latency and high write energy bring challenges for data management over it. Li et. al. (Li, Jin, Yang, Wu, & Yue, 2016) propose

an improvement over the B+-tree for PCM. For write-intensive leaf nodes, they use an overflow-node technique to reduce PCM writes. For read-intensive ones, they adjust the tree structure to remove overflow nodes to improve the read performance. The proposed B+-tree outperforms the traditional B+-tree and the overflow B+-tree.

Query Processing

Query Processing with Multi-Core CPUs

Optimization of Database Operators

Kim et al. investigated join implementations on multi-core CPUs (Kim, Sedlar, Chhugani, Kaldewey, Nguyen, Blas, Lee, Satish, & Dubey, 2009), including hash join and sort-merge join. They offered optimized implementations, which have exploited large on-die cache, thread-level parallelism, data-level parallelism, and high memory bandwidth. The hash join performs consistently over a wide range of input data sizes from 64K to 128M tuples, and it is not affected by data skewness. The throughput of more than 100M tuples per second is 17X faster than the best reported performance on CPUs, and 8X faster than that reported for GPUs. On the other hand, the optimized sort-based implementation achieves a throughput of 47M to 80M tuples per second.

Albutiu et al. proposed a suite of new massively parallel sort-merge join (MPSM) algorithms (Albutiu, Kemper, & Neumann, 2012), which are based on partial partition-based sorting. The algorithms work on the independently created runs in parallel. This way the MPSM algorithms are NUMA-affine, since all the sorting is carried out on local memory partitions. Experiments on a 32-core machine with one terabytes of main memory prove the competitive performance of MPSM on large main memory databases with billions of tuples. The algorithms outperform the Vectorwise query engine by a factor of four.

Lang et. al. (Lang, Leis, Albutiu, Neumann, Kemper, 2013) identified the major performance

problems on NUMA architectures, and they developed a NUMA aware hash join algorithm. The algorithm distributes data carefully in order to provide balanced bandwidth on the inter-partition links without architecture-specific knowledge. Experimental results show that the hash join implementation outperforms previous hash joins by a factor of more than two, resulting in an unprecedented throughput of 3/4 billion join argument tuples per second.

Broneske et. al. (Broneske, Breß, &Saake, 2014) studied the performance of different variants of the scan operator. They investigated the impacts of four code optimizations (No Branching, Loop Unrolling Vectorization, and Parallelization) and their combination on the scan operator. They found that the performance of the scan operator for different processors gets harder to predict when several code optimizations are combined, which necessitate further investigation.

Zeuch and Freytag (Zeuch, & Freytag, 2015) extensively studied performance characteristic of selection operations on modern Intel CPUs. They concluded that a cost model that takes branch mispredictions as well as cache accesses with different weights into account can give more accurate cost estimations. Such a model could be generalized to other database operations such as projections, joins, or aggregations.

It is important to decide the degree of parallelism (DOP) of an operator in database query execution plans. Gawade et. al. (Gawade, & Kersten, 2016) proposed a feedback based parallelization scheme, which identifies the most expensive operator from previous execution. Their method generates better plans and improves the utilization of multi-cores.

Execution of Queries

Xi et. al. (Xi, Mishima, Yokota, 2014) proposed CARIC-DA, a middleware for achieving higher performance in DBMSs on multi-core processors by reducing cache misses with a new cache-conscious dispatcher for concurrent queries. CARIC-DA logically range-partitions the data

set into multiple subsets. This enables different cores to access different subsets by ensuring that different DB processes are pinned to different cores, and by dispatching queries to DB processes according to the data partitioning information. In this way, CARIC-DA is expected to achieve better performance via a higher cache hit rate for each core's private cache.

Interactive applications, and periodic jobs to generate daily reports have different response time requirements. Resource management based on priorities has been proposed for disk resident databases, which typically rely on multiplexing threads on a number of processing units. However, the strategy is unfavorable for main memory database using multi-core CPUs. A large number of context switches disrupt cache conscious algorithms and have a negative impact on intra-query parallelism. Wust et. al. (Wust, Grund, Plattner, 2013) proposed a resource management framework based on a task-based query execution that avoids the cost of thread multiplexing.

Furthermore, they (Wust, Grund, Hoewelmeyer, Schwalb, & Plattner, 2014) proposed a task-based query execution model with priority-based scheduling to effectively prioritize of transactional and analytical queries in a single in-memory database instance on multi-core CPUs. They found that a larger task size for long running operators negatively affects the response time of short running queries. They therefore limit the maximum task size to control the mutual performance impact of different query classes.

Query Processing with GPUs

Govindaraju and his colleagues presented a new algorithm - GPU TeraSort (Govindaraju, Gray, Kumar, & Manocha, 2006) to sort billion-record databases using GPUs. The algorithm uses the data parallelism and task parallelism of the GPU to perform memory-intensive and compute-intensive tasks, and uses the CPU to perform I/O and resource management. On their hardware, they achieved a record of sorting 60GB for a penny.

Fang et al. explored the design variants in query co-processing using GPUs (Fang, He, Lu, Yang, Govindaraju, Luo, & Sander, 2007). They have devised a GPU Sort algorithm which is based on bitonic sorting network, a GPU-CSS tree which is based on *Cache Sensitive Search Tree*, and a GPU-based *Min Max Join*. They presented promising results of their methods. Cederman and Tsigas proposed a modified quick sort algorithm for GPU (Cederman, & Tsigas, 2009). The new quick sort algorithm outperforms radix sort and bitonic sort. GPU based quick sort is a viable method for sorting large quantities of data.

He et al. designed a set of data-parallel primitives such as scan, scatter and split, and used these primitives to implement various joins (He, Yang, Fang, Lu, Govindaraju, Luo, & Sander, 2008) including indexed/non-indexed nested-loop, sort-merge and hash joins. The GPU-based algorithms are 2-20X faster than their CPU-based counterparts.

Kaldewey et al. revisited offloading large-scale relational join operations to GPUs (Kaldewey, Lohman, Muller, & Volk, 2012). GPU-based join algorithms achieved 3-8X performance improvement over the fastest reported implementation on multi-core CPUs. In the typical scenario of hash join, i.e., when the probe table is much larger than the build table, the GPU hash join implementation could achieve 96% utilization of the bandwidth (6.3GB/s) of PCI-E generation 2. They are also trying to handle larger data sets and process more complex queries on GPUs.

Karnagel, Muller and Lohman (Karnagel, Muller, & Lohman, 2015) study offloading grouping and aggregation operators, which are dominant operations in analytics queries after joins, to GPUs. Based on a detailed performance analysis of grouping and aggregation on the GPU, they provide a parametric model for a wide range of workloads with a heuristic optimizer to automatically pick the best implementation and performance parameters at execution time.

Transaction Processing and Concurrency Control

Concurrency control is critical for correct execution of simultaneously running transactions in database systems. It is based on locking or multi versioning. According to (Harizopoulos, Abadi, Madden, & Stonebraker, 2008), locking and latching account for 30% of instruction counts in transaction processing. When multi-core CPUs are widely used, and main memory is in abundance, designing an efficient concurrency control scheme for database systems is an important work to fully release the power of multi-core CPUs. The existing works are classified into two categories, lock-based methods and multi versioning based methods.

Lock-Based Concurrency Control

Jones et al. compared two low overhead concurrency control schemes (Jones, Abadi, & Madden, 2010). The first is a light-weight locking scheme, and the second is an even lighter-weight type of speculative concurrency control. The second scheme avoids the overhead of tracking reads and writes, but sometimes conducts some work that must be roll backed eventually. Speculative concurrency control can improve throughput by up to a factor of two using a modified TPC-C benchmark compared to other methods.

Ren et al. proposed *Very Lightweight Locking* (VLL) (Ren, Thomson, & Abadi, 2012), an alternative pessimistic concurrency control scheme for main-memory database system. VLL co-locates lock information (two simple semaphores) with the raw data, and forces all locks to be acquired at once by any transaction. A selective contention analysis (SCA) protocol helps systems implementing VLL to achieve high transactional throughput under high contention workloads. Experiment results on a database running on a multi-core single machine, and a distributed database running on a shared nothing cluster, show that VLL dramatically reduces locking overhead and increase transactional throughput.

Jung et. al. presented a scalable lock manager (Jung, Han, Fekete, Heiser, & Yeom 2013) for multi-core platforms. Based on the analysis on MySQL, it is identified that latch contention within the lock manager is the bottleneck that is responsible for the performance drops when the load increases. Adoption of barrier synchronization greatly reduces the usage of latch. Locks are pre-allocated in bulk, and the lock manager only needs to perform simple list manipulations during the acquiring and releasing phases of a transaction. De-allocation of the lock data structures is also done in bulk, which enables faster lock releasing. Their implementation can scale better than standard lock manager of MySQL.

Multi Versioning Based Concurrency Control

Larson et al. introduced two efficient concurrency control methods specifically designed for main-memory databases (Larson, Blanas, Diaconu, Freedman, Patel, & Zwilling, 2011). Both use multi versioning to isolate read-only transactions from updates, but differ in how atomicity is ensured, one is optimistic and the other is pessimistic. The authors also implemented a main-memory optimized version of single-version locking for comparison. Experimental results show that although single-version locking works well when transactions are short and contention is low, the performance quickly degrades under more demanding situations. Multi versioning schemes incur higher overhead, but are less sensitive to hotspots and long-running transactions.

Hyper database (Kemper, & Neumann, 2011) uses copy-on-update to preserve consistent snapshot to support OLAP queries in an OLTP main memory database. Hyper yields transaction rates as high as 100,000 per second and very fast OLAP query response times on a single system, executing hybrid workloads in parallel (using TPC-C and TPC-H benchmarks).

When the number of CPU cores increases, previous implementation of serializable snapshot

isolation does not scale well due to latch contention on internal data structures. Han et. al. proposed to detect the required read/write conflict conditions at runtime without the need to latch the transaction manager's internal structures (Han, Park, Jung, Fekete, Rohm, & Yeom, 2014). Their method scales well on an Intel 4-way 32 core machine. It outperforms their original implementation up to 20X, and maintaining high throughput when serving 500 clients.

Systems implementing snapshot isolation (SI) usually lack the support of full serializability. Neumann et. al. proposed a method to add serializability to existing snapshot isolation implementations (Neumann, Muhlbauer, & Kemper, 2015). The method is based on the adaptation of precision locking. It verifies that the writes of recently committed transactions do not intersect with the read predicate space of a committing transaction, by updating data in-place and storing versions as before-image deltas in undo buffers. Their MVCC achieved fast processing of point accessing and read-heavy transactions.

Kim et. al. proposed ERMIA (Kim, Wang, Johnson, & Pandis, 2016), a memory-optimized database system built from scratch to handle mixed workloads. They adopt snapshot isolation concurrency control instead of lightweight optimistic concurrency control (OCC) to coordinate heterogeneous transactions, and provides serializability when needed. ERMIA achieves comparable or superior performance and near linear scalability for a variety of workloads, compared to a lightweight OCC-based system.

Recovery

When a power-off takes place, the contents in the main memory database (except NVRAM) will disappear. Recovery system is a critical component for main memory databases. The goal of the recovery system is to recover the whole database as soon as possible after failures, without blocking of normal transaction execution too much when doing bookkeeping.

Recovery system of disk resident databases is mature and efficient. Usually it includes three components i.e. logging, checkpointing, and recovery. Researchers don't build recovery systems for main memory databases from scratch, but they borrow ideas from disk resident databases. Levy and Silberschatz presented a page-based incremental restart algorithm (Levy, & Silberschatz, 1992), which enables the resumption of transaction processing as soon as possible after the system restarts. Data pages are recovered individually and according to the access demands of the post-crash transactions. Lin and Dunham proposed a segmented fuzzy checkpoint (SFC) scheme (Lin, & Dunham, 1996), which uses a moving window to locate the redo-point more efficiently than traditional fuzzy checkpointing approaches. SFC can significantly reduce the log processing time during restart, only slightly degrading the system performance.

Lee, Kim, and Cha introduced a parallel recovery method (Lee, Kim, & Cha, 2001), which is based on a differential logging technique. Differential logging has two nice properties of commutative and associative. Logging records can be combined in any order and written to disks in parallel, which speeds up the execution of transactions. During recovery, the applying of log records to the data pages does not need to comply with the serialized order, thus different pages can be recovered in parallel, which accelerates the recovery process.

In modern high-throughput transaction processing systems, as transaction throughputs get higher, fine-grained, record-oriented ARIES-style physiological logging starts to take a substantial fraction of the overall transaction execution time, it is no longer the optimal way to recover a database system. Malviya et. al. (Malviya, Weisberg, Madden, Stonebraker, 2014) proposed a light weight command logging technique which only records the commands that were executed. The database is recovered by loading of a transactional consistent checkpoint and replaying the commands in the log. Command logging yield significantly

higher throughput at run-time. It offers 1.5X higher throughput than a main memory optimized implementation of ARIES-style physiological logging with TPC-C benchmark.

High speed byte addressable non-volatile memory allows people to rethink the durability mechanism of main memory databases. Schwalb et. al. (Schwalb, Kumar, Dreseler, Anusha, Faust, Hohl, Berning, Makkar, Plattner, & Deshmukh, 2016) proposed a new database Hyrise-NV, which updates data and index transactionally on NVRAM using multi version data structures. Hyrise-NV can instantly recover the database independently of its size, allowing the recovery of a table with 10 million rows in less than 100 ms.

Database Industry Efforts

Database management systems such as SQL Server was designed and implemented in the days when main memory was small, data lived in disks, machines had a single slow processor, and OLTP was the only workload. Nowadays the situation is changing. People have large memories, plenty of cores, and transactional and analytic workloads are equally important. Observing the potential of providing higher query processing performance by adapting database implementation to new hardware, database vendors and startups try to revise their current flagship product under new hardware environments or invent new databases.

Microsoft adapts SQL server to today's hardware by adding new features of column store indexes and in-memory tables (Larson, Hanson, & Zwilling, 2015).

IBM provided in memory BLU Acceleration for DB2 to improve its performance on mixed OLTP and BI analytics workloads (Barber, Lohman, Raman, Sidle, Lightstone, & Schiefer, 2015). Data is encoded and packed densely into bit-aligned vectors and kept in system cache, which can exploit SIMD (single instruction multiple data) instructions in query processing. BLU assigns independent data structures to each thread, incurring low synchronization cost, and achieves

scalable multi-core parallelism. BLU improves the performance on complex analytic queries by 10 to 50 times, on UPDATE and DELETE up to 112 times, compared to row organized tables.

Oracle provides a dual format in memory database (Lahiri, Chavan, Colgan, Das, Ganesh, Gleeson, ..., & Zait, 2015). The database allows data to be maintained in row-wise and columnar formats simultaneously and maintain transactional consistency between them. It employs a variety of optimizations including various levels of compression, SIMD vector processing, and in-memory storage indexes. In-memory column format achieves per CPU core scan speeds exceeding many billions of rows per second, which enables further query optimizations such as in memory aggregation. Costly joins and aggregations can be converted into a series of filtered scans. There is no need to create indexes. OLTP DML operations achieve a substantial speedup by eliminating index maintenance cost.

HP Lab envisions that next generation of servers will have thousands of cores, large DRAM and huge NVRAM, now no existing database is designed to running on such hardware. They developed a new database system FOEDUS (Kimura, 2015). It scales up in-memory database technologies, and allows transactions to manipulate data stored in both DRAM and NVRAM efficiently. The throughput of FOEDUS on a large NUMA machine with 240 physical cores is multiple orders of magnitude higher than H-Store with anti-caching using the TPC-C benchmark.

Besides the above mentioned systems, several other database systems deserve attention. Vectorwise is the commercialization of open sourced analytic main memory database of Monet. VoltDB is the commercialization of open sourced main memory database of H-Store, and it is aimed at OLTP workloads. SAP's HANA is an in memory database for high performance processing of hybrid workloads (Faerber, Dees, Weidner, Bauerle, & Lehner, 2015). MemSQL (Shamgunov, 2014) is a distributed in memory database, also supporting real time processing of OLTP and OLAP workloads.

FUTURE RESEARCH DIRECTIONS

Hardware-conscious database design is still a blossoming research direction when new hardware keeps emerging. Innovations on low level of storage and index, to up level of query processing, which fully utilize characteristics of new hardware, will improve the performance of database. To achieve higher performance, some researchers even accelerate database operations using specific Field Programming Gate Array (FPGA) (Mueller, & Teubner, 2009).

Another research direction is keeping database system in an independent progress track. Some researchers design general data models and query processing algorithms that are adaptive to various hardware, with the expectation that database can achieve consistently high performance on different hardware.

CONCLUSION

There are several trends in hardware development in recent years. Multi-core CPUs provide massive parallelism. GPUs provide even more parallelism and they are also used in data intensive tasks. With the price going down, people now install very large memory in a single machine, allowing them to keep more data in memory. Various non-volatile memory techniques become mature. High performance non-volatile memory and solid state disks introduce more intermediate levels in the memory hierarchy.

All these hardware advancements require that database systems are revised to fully leverage the power of hardware for higher performance. Some efforts of database research community are presented in this chapter. The techniques include data layouts, index schemes, query processing techniques, transaction processing & concurrency control methods, and recovery techniques, which accelerate data exchange between different levels of memory hierarchy and leverage parallelism of multi-core CPUs and GPUs.

KEY TERMS AND DEFINITIONS

Cache Oblivious: Database data/index layouts and processing techniques those are independent of parameters of memory hierarchy.

Cache Sensitive (Cache Conscious): Database data/index layouts and processing techniques those are adaptive to the parameters of memory hierarchy.

DSM: Decomposition Storage Model, vertically partitions an n-attribute relation table into columns, each of which is fetched only when queries need it.

GPU/GPGPU: General Purpose Graphics Processing Unit, is not only used for graphic

processing, but also for other tasks such as data processing.

Multi-Core CPU: Several cores are manufactured on a single die for higher performance by parallelism.

MVCC: Multi versioning concurrency control coordinates execution of concurrent transactions by maintaining multiple versions of the same data to avoid mutual interference among these transactions.

NSM: N-ary Storage Model, stores records contiguously starting from the beginning of each disk page, and uses an offset (slot) table at the end of the page to position the beginning of each record (row). NSM has poor cache performance because it loads the cache with unnecessary attributes.

NVRAM: Non-volatile memory is some type of computer memory that can keep information after the power is turned off.

PAX: In Partition Attributes Across, a table is firstly horizontally partitioned into pages, in each page all values of each attribute are grouped together, which greatly improves cache performance.

Ensemble Clustering Data Mining and Databases

Slawomir T. Wierzchon

INTRODUCTION

Clustering is an exploratory activity relying upon dividing a given collection X of objects, or entities, into a set of categories, called groups or clusters, in such a way that any two objects placed in the same group have more in common than any two objects assigned to different groups. Consensus clustering has been proposed to overcome some drawbacks of individual clustering algorithms. Usually we assume that the clusters are disjoint subsets of X such that the objects belonging to a single cluster are sufficiently similar to each other (i.e. the clusters should be homogeneous), while objects from different clusters should be sufficiently diversified (i.e. clusters should be well separated). Splitting given collection into disjoint clusters is termed hard clustering. Otherwise we say about soft clustering, i.e. – depending on the formalism used – probabilistic or fuzzy clustering.

The most popular clustering algorithm is the k -means algorithm producing hard partitions – consult (Jain, 2010) for historical background and deeper discussion of its current improvements and variations. Soft version of the algorithm, called fuzzy c -means, was proposed by Bezdek (1981). This author used letter c to name the number of clusters, hence the name of the algorithm. Both the algorithms minimize the squared-error criteria. They are computationally efficient and do not require the user to specify many parameters. However, there are three main disadvantages of both the algorithms. First, they require that the entities must be represented as points in n -dimensional Euclidean space. To alleviate this assumption Hathaway, Davenport and Bezdek (1989) introduced

relational version of fuzzy c -means algorithm: instead of the distance between the points representing the objects, a similarity measure between all pair of objects was used. In case of hard partitions the k -medoids algorithm was proposed: here a dissimilarity measure between pairs of objects replaces the distance measure – see e.g. Section 14.3.10 in (Hastie, Tibshirani, & Friedman, 2009). The second disadvantage results from the way in which objects are assigned to the clusters. Namely, in case of hard k -means each object is located to the cluster with nearest centroid (empirical mean of the cluster). Thus resulting clusters are spherical (more precisely, they are Voronoi regions). A similar assignment rule is used in the fuzzy c -means algorithm. Third disadvantage is that, the clusters should be of approximately similar cardinality and of similar shape. In case of unbalanced clusters erroneous results are frequently obtained. Similarly, if one cluster is located within a ball of small radius and the second – within an ellipsoid with one axis much greater than others, we can obtain erroneous results. Examples of “easy” and “difficult” data are depicted in Figure 1. Left panel presents compact, well separated, convex and linearly separated clusters, while non-convex clusters that are not linearly separated are shown in right panel.

To avoid these disadvantages, the ideas of ensemble methods used by machine learning community to improve results of classification methods, have been adapted to the requirements of clustering. In general, the ensemble methods use multiple models to obtain better predictive performance than could be obtained from any of the constituent models. A nice overview of these

Figure 1. Examples of data that are “easy” (left panel) and “difficult” (right panel) to the *k*-means algorithm

methods used in machine learning can be found e.g. in (Zhou, 2012). When transposed to the field of unsupervised learning (i.e. clustering) this idea translates to collecting multiple partitions of the same data. By combining these partitions, it is possible to obtain a good data partition even when the clusters are not compact and/or not well separated (Jain, 2010). Consensus clustering seems to be especially recommendable to analyze huge datasets. As noted in (Hore, Hall, & Goldgof, 2009): “The advantage of these approaches is that they provide a final partition of data that is comparable to the best existing approaches, yet scale to extremely large datasets. They can be 100,000 times faster while using much less memory.”

Irregular, of complex shape and structure, clusters is only one aspect of the problem. The other is strictly pragmatic. In some applications we are simply “knowledge consumers”, i.e. we use a knowledge created by others. In the context of clustering such knowledge is represented by a set of partitions, and consensus clustering is used to integrate these partitions into consistent form. Strehl and Ghosh (2003) propose the term “Knowledge reuse” to label such an activity. Further, the knowledge acquired in such a way may be prepared using different points of view, different needs or different criteria, and it may be generated by large number of sources. Thus these authors distinguish between feature distributed clustering (FDC) and object distributed clustering (ODC). In first case it is assumed that all the data are available, but each time they are clustered using only a subset

of features, or attributes, characterizing each piece of data. In the second case a fixed set of attributes is used but the collection of data vastly exceeds the size of a typical single memory. So, different partitions are obtained by using only pieces of the whole collection. Again consensus clustering allows consolidate these different clusterings into consistent partition (Hore, Hall, & Goldgof, 2009). A nice illustration of the FDC principle is e.g. the study by Helsen and Green (1991) who applied cluster analysis to define market segments for a new computer system. The dispersions in the opinions collected from 319 users resulted in different partitions. To make final judgments these authors used a Monte-Carlo based simulation method which can be classified as a precursor of consensus clustering.

To summarize, consensus clustering (called also ensembles clustering, or clustering aggregation) is a general purpose method that can be used to improve both the robustness and the stability of partition of large multidimensional datasets. As observed by Howard Firestone (2012): “The advantages of Cluster Ensemble include:

- Combining groupings from alternate and dissimilar sets of variables (e.g., demographics, lifestyle batteries, desired benefits or needs, etc.).
- Including a variety of clustering techniques when building the ensemble.
- Incorporating legacy clusters that are based on internal data.
- Uncovering better, more robust cluster solutions that are less sensitive to sample variations and outliers.
- Being able to find solutions that would not have been uncovered using a single approach.”

In this article we briefly review different approaches to the task of consensus clustering. After careful formulation of the problem we briefly characterize its components, that is: (a) the methods of obtaining different clustering, (b) the

methods of representing acquired knowledge, and (c) the methods of aggregating this knowledge into a consistent and manageable form. Some remarks on available software are provided.

A comprehensive introduction to the subject can be found e.g. in Ghosh and Acharya (2011), Goder and Filkov (2008), Vega-Pons and Ruiz-Shulcloper (2011), or in Section 8.3 of Kuncheva (2004). Gionis, Mannila, and Tsaparas (2007) provide a review of different applications of consensus clustering.

BACKGROUND

The problem of consensus clustering is formulated as follows, see Fred and Jain (2005), Filkov and Skiena (2004), or Meyer and Wessell (2012) for details. Suppose $X = \{x_1, \dots, x_m\}$ is a set of m objects. Let $\mathbf{P} = \{\mathbf{P}^1, \dots, \mathbf{P}^K\}$ be a family of K partitions obtained e.g. by using K different clustering algorithms. We call $\mathbf{P}$ the clustering ensemble. Each partition $\mathbf{P}^i$ splits the dataset into k_i clusters, i.e. $\mathbf{P}^i = \{C_1^i, \dots, C_{k_i}^i\}$, and k_i is the number of clusters in i -th partition. The problem is to find an agreed or compromised partition, $\mathbf{P}^*$, using the information available in the ensemble $\mathbf{P}$. Such a partition should satisfy at least two properties:

1. Consistency with the clustering ensemble $\mathbf{P}$.
2. Robustness to small variations in $\mathbf{P}$.

The first property states that the partition $\mathbf{P}^*$ should be as close as possible to all the partitions $\mathbf{P}^i$ from $\mathbf{P}$. In general, it is an NP-complete optimization problem known as median partition, consult (Cristofor & Simovici, 2002) for details. Some heuristic approaches to such a problem were proposed in the papers quoted at the beginning of this section. The second property requires that the number of clusters and the cluster membership in $\mathbf{P}^*$ should be resistant, or invariant, to small

perturbations in $\mathbf{P}$. Additionally, Fred and Jain (2005) introduce third requirement: The partition $\mathbf{P}^*$ should be consistent with ground truth information (true cluster labels of patterns), if available. Other variants of the compromise partition could be obtained by introducing extra requirements on $\mathbf{P}^*$, e.g. a fixed number of clusters in $\mathbf{P}^*$.

Figure 2 illustrates the problem. Original data, depicted in top left panel, present three nested circles (i.e. non-convex clusters): outer circle consists of 200 points, middle circle – of 100 points, and inner circle consists of 50 points. Since the data are not linearly separated, the k -means algorithm cannot identify proper groups. The panels (b) – (d) depict exemplary partitions obtained from k -means algorithm with different values of k . In this (simplified) case the family $\mathbf{P}$ consists of three partitions: $\mathbf{P}^1$ splits the data set into two subsets (Figure 2b), $\mathbf{P}^2$ – into three subsets (Figure 2c), and $\mathbf{P}^3$ – into four subsets (Figure 2d). The objects assigned to different clusters are depicted by different markers painted in different color. The problem relies upon “smart” integration of these partial pieces of evidence to obtain proper clustering into three groups.

FINDING A CONSENSUS CLUSTERING

Solving the problem of consensus clustering requires answering at least three questions: (i) how to obtain different partitions $\mathbf{P}^1, \dots, \mathbf{P}^K$, (ii) how to represent the family of such partitions into manageable form, and (iii) how to extract the partition $\mathbf{P}^*$ from $\mathbf{P}$? Below we review possible answers to these questions.

Obtaining a Set of Partitions

The motivations for using consensus clustering, described in the “Introduction,” imply also the ways of obtaining a family of partitions. First, the natural sources of different partitions are different views on data. This is typical in applications like

Figure 2. The problem of consensus clustering: (a) original data, (b) – (d) partitions obtained by using the k -means algorithm with $k = 2, 3$, and 4

e.g. market segmentation, where customers may be segmented according to their needs, attitudes, demographic profiles, etc. – see again (Firestone, 2012) and (Helsen & Green, 1991). Bioinformatics (Goder & Filkov, 2008), (Grothjær *et al.*, 2006), Internet security (Zhuang *et al.*, 2012), or text clustering (Marcacini, Domingues, & Rezende, 2013) are another fields where different views should be aggregated to extract complicated clusters from highly dimensional data.

A general recipe to obtain different views is multiple application of any single algorithm with different initializations or by varying its (hyper)-parameters. Averaging over such formulated ensemble enables to extract quite complicated clusters, (Fred & Jain, 2005). Greene *et al.* (2004) lists a number of ways, in which such multiple runs can be realized. Focusing on k -means algorithm they distinguish between:

1. **Plain Method:** Use randomly initialized centroids in each run of the algorithm.
2. **Random- k Method:** Use randomly selected values of the number of clusters, k , from a user-specified interval. Such a method was also mentioned by Fred and Jain (2005). In their experiments these authors used k in the range $\{2, \dots, k_0+10\}$, where k_0 is the true number of clusters in a given dataset.
3. Random- $k+$ method is inspired by the observation that a collection of clusterings generated at a much higher resolution than the value of k_0 can provide better results. Thus Greene *et al.* (2004) used k in the range $\{2, \dots, k_0+30\}$.

Another source of variability is provided by using different clustering methods. Greene *et al.* (2004) used in their experiments standard k -means,

k -medoids and a fast “weak clustering” algorithm. In this last, highly simplified algorithm, k centroids are chosen at random and the remaining entities from the set X are assigned to the cluster with the nearest centroid. Such an allocation is performed only once with no further improvements. Other choices of clustering algorithm are possible; however their simplicity is the main criterion when selected.

Furthermore, variants of other methods developed for supervised learning can be used. Review of such method can be found in Kuncheva (2004). Greene *et al.* (2004) tested four of them:

4. **Bagging:** The subsets of the original data are generated by randomly selecting instances with replacement. Each subset is clustered separately.
5. **Random Subspacing:** Relies upon generating partitions using a randomly selected subset of the original attributes or dimensions.
6. **Random Projection:** Another effective ensemble creation method proposed in Fern and Brodley (2003), and used e.g. in Topchy, Jain, and Punch (2003). It produces a set of dissimilar clusterings by randomly projecting the data onto a subspace of dimension n' randomly selected from the set $\{1, \dots, n\}$.
7. **Heterogeneous Ensembles:** Here each partition is generated using a different clustering algorithm.

Minaei-Bidgoli *et al.* (2014) compare the efficacy of both bootstrap and subsampling (sampling without replacement) techniques in conjunction with several aggregating algorithms (discussed later). They observed that small subsamples generally suffice to represent the structure of the entire data set in the framework of clustering ensembles. Subsamples of small size can reduce computational cost for tasks with distributed sources of data. A unified framework for producing multiple partitions is presented in (Topchy *et al.*, 2005).

Representing Clustering Ensemble

Perhaps the simplest method, used e.g. in (Fred & Jain, 2005), is to form a symmetric co-association matrix A of size $m \times m$ with the entries a_{ij} denoting how many times the elements i and j were clustered together. If necessary, each entry can be divided by K , the number of clusterings, so a_{ij} 's are numbers belonging to the interval $[0, 1]$. Furthermore, we can assign weights, w_r , expressing e.g. a credibility, or simply, importance of each partition, $\mathbf{P}^r$. Then the a_{ij} 's are weighted sums of the form

$$a_{ij} = \frac{1}{K} \sum_{r=1}^K w_r \delta(C_i^r, C_j^r) \quad (1)$$

where C_i^r denotes the cluster to which i -th object has been assigned in r -th partition and $\delta(a, b) = 1$ if $a=b$, and $\delta(a, b) = 0$ otherwise. The main disadvantage of such an approach is the necessity of computing $m(m-1)/2$ elements of the (symmetric) matrix A .

That is why we rather compare partitions by using some measure $q(\mathbf{P}^i, \mathbf{P}^j)$ of agreement between the pairs $\mathbf{P}^i$ and $\mathbf{P}^j$ of partitions – consult Kuncheva (2004), Meila (2007), or Vinh, Epps, & Bailey (2010) for a review of different indices. Generally we distinguish among three classes of measures: based on pair counting, on set-matching, and information theoretic measures. Many of the indices belonging to the first class, like Rand index or its modifications, are popular in information retrieval, (Manning, Raghavan, & Schütze, 2009).

To give an example, denote n_{11} the number of pairs of objects from X , which were assigned to the same cluster in the partition $\mathbf{P}^i$ and to the same cluster in $\mathbf{P}^j$. Let n_{00} be the number of pairs of objects from X that are in different clusters in the partition $\mathbf{P}^i$ and are also in different clusters in $\mathbf{P}^j$. Both n_{00} and n_{11} are agreement quantities as in both partitions the pair of objects have been found to be either similar enough so as to be placed in the same cluster, or dissimilar enough so as to be placed in different clusters. We can define also

the two disagreement quantities n_{01} (meaning the number of pairs of objects that are in different cluster in $\mathbf{P}^i$ and in the same cluster in $\mathbf{P}^j$), and n_{10} (defined symmetrically). Then the Rand index, $R(\mathbf{P}^i, \mathbf{P}^j)$, is defined as follows:

$$R(\mathbf{P}^i, \mathbf{P}^j) = \frac{2(n_{00} + n_{11})}{m(m-1)}. \quad (2)$$

$R(\mathbf{P}^i, \mathbf{P}^j) = 1$ if the partitions agree completely, but does not have a constant value for the case when both partitions are drawn at random. To correct this disadvantage so-called adjusted Rand index was introduced, but its use also causes some problems, (Meila, 2007). Goder and Filkov (2008) used another distance defined as:

$$D_{GF}(\mathbf{P}^i, \mathbf{P}^j) = n_{01} + n_{10} \quad (3)$$

arguing that it is computable in linear time (with respect to the number of elements m), and that it can be updated very fast following one element moves in set partitions (this last property is important when the local search heuristics are used to optimize the distance).

Set-matching based measures, are based on finding matches between clusters in the two partitions. A popular measure is the classification error rate used e.g. in supervised learning. Several other indices are discussed in Meila (2007). Unfortunately, all these indices suffer from two major problems: (i) the number of clusters in the two partitions may be different, and (ii) even when the numbers of clusters are the same, the unmatched part of each matched cluster pair is still put outside consideration.

Lastly, the information theoretic measures are distinguished by their strong mathematical foundation, and ability to detect non-linear similarities. This class of measures has been popularized through the works of Strehl and Ghosh (2003) and Meila (2007), among others. Given two partitions, $\mathbf{P}^i, \mathbf{P}^j$, define n_{rs} to be the number of objects that are common to clusters $C_r^i \in \mathbf{P}^i$, and $C_s^j \in \mathbf{P}^j$. The cardinality of r -th cluster in the partition

$\mathbf{P}^i$ is denoted $n_{r\cdot} = \sum_s n_{rs}$, the cardinality of s -th cluster in the partition $\mathbf{P}^j$ is denoted $n_{\cdot s} = \sum_r n_{rs}$. These cardinalities can be easily converted into the estimates of probabilities p_{rs} , $p_{r\cdot}$, and $p_{\cdot s}$ by dividing corresponding values by the cardinality m . Then we can define the entropy of each partition:

$$H(\mathbf{P}^i) = \sum_{r=1}^{k_i} \frac{n_{r\cdot}}{m} \log \frac{n_{r\cdot}}{m},$$

$$H(\mathbf{P}^j) = \sum_{s=1}^{k_j} \frac{n_{\cdot s}}{m} \log \frac{n_{\cdot s}}{m} \quad (4)$$

and the mutual information between the two partitions

$$I(\mathbf{P}^i, \mathbf{P}^j) = \sum_{r=1}^{k_i} \sum_{s=1}^{k_j} p_{rs} \log \frac{p_{rs}}{p_{r\cdot} \cdot p_{\cdot s}} = \sum_{r=1}^{k_i} \sum_{s=1}^{k_j} \frac{n_{rs}}{m} \log \frac{m \cdot n_{rs}}{n_{r\cdot} \cdot n_{\cdot s}} \quad (5)$$

Meila (2007) gives a nice interpretation of this quantity. As there is no upper bound for the index I , Strehl and Ghosh (2003) proposed its normalized version

$$NMI(\mathbf{P}^i, \mathbf{P}^j) = \frac{I(\mathbf{P}^i, \mathbf{P}^j)}{\sqrt{H(\mathbf{P}^i) \cdot H(\mathbf{P}^j)}}. \quad (6)$$

This is a number from $[0,1]$, and such that $NMI(\mathbf{P}, \mathbf{P}) = 1$.

Meila (2007) introduced so-called variation of information

$$VI(\mathbf{P}^i, \mathbf{P}^j) = H(\mathbf{P}^i) + H(\mathbf{P}^j) - 2I(\mathbf{P}^i, \mathbf{P}^j), \quad (7)$$

which is a metric. Wu *et al.* (2009) suggested to use its normalized variant $NVI(\mathbf{P}^i, \mathbf{P}^j) = VI(\mathbf{P}^i, \mathbf{P}^j) / [H(\mathbf{P}^i) + H(\mathbf{P}^j)]$.

Now, let $q(\mathbf{P}, \mathbf{P}^i)$ be one of such defined measures of similarity, for instance, let $q(\mathbf{P}, \mathbf{P}^i) = NVI(\mathbf{P}, \mathbf{P}^i)$. We can introduce a combined quality function

Figure 3. Method of Meyer and Wessell (2012) applied to the data from Figure 2: (a) visualization of the double stochastic matrix P , (b) final partition obtained from this matrix

$$q(\mathbf{P}, \mathbf{P}) = [w_1 q(\mathbf{P}, \mathbf{P}^1) + \dots + w_K q(\mathbf{P}, \mathbf{P}^K)]/K, \quad (8)$$

and define the target partition $\mathbf{P}^*$ as such a partition which optimizes the index (8).

Consensus Function

By consensus function we mean a mapping of a given set of partitions $\mathbf{P}$ to a consensus representative $\mathbf{P}^*$. Again the simplest (conceptually) way to obtain such a representative is to use the co-association matrix A and treat it as a similarity matrix. Such a matrix can be thus clustered in a number of ways. Particularly, hierarchical clustering methods with single-link, complete-link, and average-link criteria could be used (Fred & Jain, 2005; Kuncheva, 2004). Strehl and Ghosh (2003) proposed three other graph-based approaches. Their adaptation to fuzzy consensus clustering is given in Punera and Ghosh (2008). Recently Meyer and Wessell (2012) introduced a method inspired by Simon-Ando theory of variable aggregation. This method reduces to finding best approximation of the co-association matrix A by a doubly stochastic matrix P , i.e. a matrix which rows and columns sum to 1. Extracting block-diagonal structure of this matrix reveals cluster structure of a given dataset. Figure 3 illustrates

the effect of such a procedure when applied to the data from Figure 2a.

Another group of methods uses the quality function (8) and searches for the optimal partition. Kuncheva (2004) provides a concise review of such approaches. Goder and Filkov (2008) search for the partition that is in minimal distance to all the partitions from $\mathbf{P}$ (i.e. they use the D_{GF} distance). These authors review a number of heuristics solving such stated task. What important, they have implemented these heuristics (the code is publicly available) and compared their performance in terms of efficacy and efficiency on many real and artificial datasets. They conclude that the clustering-based methods are generally faster, while the local-search heuristics result in a better performance. Thus, they propose an efficient hybrid algorithm, a greedy local search method starting from an initial consensus provided by the average link clustering. Cristofor and Simovici (2002) proposed to use genetic algorithm to find target partition.

FUTURE RESEARCH DIRECTIONS

Consensus clustering is a method proposed for improving robustness, stability and accuracy of clustering real data. In addition to many works

on this subject, a number of publicly software is available. For instance Goder and Filkov (2008) have written a C++ library for computing set partitions. MATLAB implementations are provided by Yu, Wong, and Wang (2007), Grotkjær *et al.* (2006), and Strehl (2003). Hornik (2005) offers elaborated implementation in R language, and Simpson, Armstrong, and Jarman (2010) describe an R package for analyzing microarray data. Lastly, Marcacini, Domingues, and Rezende (2013) provide a Java package for text mining.

Due to the unsupervised nature of the problem it is not possible to suggest the best consensus clustering method. But choosing a proper method would be easier if there was the theoretical foundation of combining multiple clustering results. Although a step toward this direction was suggested by Masson and Denoeux (2011), a solution to this problem is still in its early stages. Apart theoretical foundation, improving computational complexity in aggregating partial results seems to be an important investigation in future. Harnessing Nature-based methods to solve this task seems to be an intriguing direction – see e.g. Ghaemi *et al.* (2011) for a recent proposition. Another direction is initiated by Gullo, Domeniconi, & Tagarelli (2013). These authors suggest to use so-called projective clustering to aggregate different data partitions. On the other hand, Yousefnezhad and Zhang, D. (2015) proposed a novel framework for clustering problems, by exploiting some concepts from the areas of community detection and graph based clustering. Other advanced topics, like ensemble methods for semi-supervised learning, are discussed in Chapter 8 of (Zhou, 2012).

CONCLUSION

A solution returned by a single clustering algorithm is inevitably biased due to the peculiarities of such an algorithm. Consensus clustering was proposed to overcome this drawback. In addition to improving robustness and stability results it is perfectly fitted to integrate solutions from mul-

tle distributed sources of data. Furthermore this approach can also be used in multiobjective clustering as a compromise between individual partitions obtained by using conflicting objective functions.

KEY TERMS AND DEFINITIONS

Cluster Analysis: It is an instance of unsupervised learning. In practice cluster analysis reduces to partitioning a given data set into an appropriate number of meaningful groups. However, the very nature of clustering is weakly understood. Consult e.g. the papers collected by Ben-David, *et al.* (2009), or Henning (2015).

Entropy: In information theory this notion, introduced by Claude Shannon, is used to express unpredictability of information content. For instance, if a data set containing n items was divided into k groups each comprising n_i items, then the entropy of such a partition is $H = p_1 \log(p_1) + \dots + p_k \log(p_k)$, where $p_i = n_i/n$. In case of two alternative partitions, the mutual information is a measure of the mutual dependence between these partitions.

NP-Hard Problems: A notion used in computational complexity theory. It denotes a class of problems that are, informally, “at least as hard as the hardest problems in NP”. The shorthand NP means “non-deterministic polynomial-time.”

Supervised Learning: The problem of supervised learning is formulated as follows: Let $X = \{x_1, \dots, x_m\}$ be a set of m objects or entities. Suppose these objects come from k classes and the membership to each object to exactly one class is known in advance. Then such a set is termed a training set T . It has the form $T = \{(x_1, l_1) \dots, (x_m, l_m)\}$ where l_i denotes the label of a class to which i -th object belongs. The aim of supervised learning is to find a mapping $f: X \rightarrow L$, such that $f(x_i) = l_i$, for all $i = 1, \dots, m$. The function f is said to be decision function or decision rule. If the labels l_i are not known we say about unsupervised learning. Its task is to discover a structure in the set X .

Unsupervised Learning: Contrary to the supervised case we have only the data set $X = \{x_1, \dots, x_m\}$ of m objects or entities. The aim of unsupervised learning is to find inner structure in this set, or equivalently, to find some regularities in this set. Clustering is a possible tool used to extract such information, but other approaches (e.g. self organizing maps) may be used as well. If the labels l_i are known for a (usually small) subset of X we are faced with semi-supervised learning.

Voronoi Regions: Suppose that the objects from the set X are represented as points in n -dimensional Euclidean space $\mathbf{R}^n$, and stands for the centroid (empirical mean) of i -th cluster C_i . The Voronoi region associated with this centroid is the set of all points in $\mathbf{R}^n$ whose distance to is not greater than their distance to the other centroids.

Graph-Based Concept Discovery

INTRODUCTION

Multi-relational data mining (MRDM) (Džeroski, 2003) is concerned with discovering patterns hidden in data that is stored in relational format, i.e. as a database. One of the most commonly addressed tasks in MRDM is concept discovery (Džeroski, 2003), where the problem is inducing logical definitions of a specific relation, called *target relation*, in terms of other relations called *background knowledge*. Given a database consisting of kinship relations such that *mother* is the target relation; *father* and *wife* and are among background knowledge, a typical concept discovery system would induce a concept rule like *mother(A,B):-father(C,B), wife(A,C)*.

Concept discovery can be considered as a predictive learning task where target relation instances are generally represented as ground facts, background knowledge is represented either intensional or extensional; and concept descriptors are usually in the form of Horn clauses. Logic-based, more specifically Inductive Logic Programming (Muggleton, 1991) (ILP)-based, and graph-based approaches are two competing counterparts in concept discovery. ILP-based approaches (Quinlan, 1990; Muggleton 1995) benefit from the powerful data representation framework provided by first order logic and the easily interpretable concept descriptors they discover. Such systems suffer from long running times mainly due to evaluation of the large search space they

build, and are vulnerable to miss certain concept descriptors due to the local minima problem (Richards & Mooney, 1992). Graph-based approaches (Gonzalez, Holder, & Cook, 2002; Yoshida & Motoda, 1995) also provide powerful mechanisms to represent relational data and have heavily studied algorithms that can be modified to find concepts in graph data. Graph-based concept discovery systems can be classified as substructure-based approaches and pathfinding-based approaches. In the former, the assumption is that concepts should appear as frequent substructures in a graph, hence computationally expensive algorithms like subgraph isomorphism need to be employed. The assumption behind the systems that fall into the second category is that concepts should appear as finite length paths that connect certain vertices, hence such system need to employ path-profiling algorithms.

In this chapter we aim to introduce concept discovery problem and discuss several issues of graph-based concept discovery in depth. To this aim, in this chapter, we provide fundamentals of concept discovery in general, and in detail discuss state-of-the-art graph-based concept discovery methods by means of (i) data representation, (ii) search method, and (iii) concept evaluation mechanism.

The rest of the article is organized as follows. In the second section, an introduction to concept discovery and definitions of fundamental terms in concept discovery are provided; the concept

discovery problem is formally expressed. In the third section, classification of graph-based concept discovery approaches is provided; knowledge representation, search methods, and evaluation methods are introduced. In this section a running example is provided for a state-of-the-art pathfinding-based system presented in (Abay, Mutlu, & Karagoz, 2015a). In the fourth section, possible research directions for graph-based concept discovery are presented.

BACKGROUND

Multi-relational data mining is concerned with inducing patterns hidden in data stored in relational model, i.e. in a relational database. Traditional data mining algorithms are designed to work on flat files and cannot directly be work on such data. Two main directions in mining relational data are (i) converting the relational data into single table and then employing propositional learners (Kramer, Lavrač, & Flach, 2001), and (ii) developing new algorithms that can directly work on relational data (Džeroski, 2003). The main disadvantage of the first approach is the possible loss of information

during propositionalization process. Most of the algorithms that belong to the second direction have their roots in ILP. ILP is concerned with inducing general theories from examples. It was first proposed for learning binary classification rules, but now can model more complex data mining problems.

One of the most commonly addressed tasks in MRDM is concept discovery. Concept is a set of frequent patterns embedded in the features of the concept instances and its relations to other objects (Toprak, Senkul, Kavurucu, & Toroslu, 2007). *Completeness* and *consistency* are two measures to test quality of concept descriptors (Muggleton & De Raedt, 1994). A concept descriptor is called complete if it explains all of the positive target instances and consistent if it explains none of the negative target instances. As real world data is usually noisy, completeness and consistency are hard to meet in their pure definitions, hence they are extended to explain as many positive target instances as possible and as few negative target instances as possible, respectively (Pham & Afify, 2006). Concept discovery systems generally follow iterative covering approach to induce concept descriptors. They start with an initial hypothesis

Algorithm 1. Generic concept discovery algorithm

```

Input: E: target instances, B: background knowledge
Output: H: Complete and consistent concept descriptors
1: while E  $\neq \emptyset$  or H'  $\neq \emptyset$  do
2:     H' =  $\emptyset$ 
3:     Start with an initial hypothesis set H'
4:     for all h  $\in$  H' do
5:         refine(h)
6:         evaluate(h, B)
7:         if good(h) then
8:             cover(E, h)
9:             H' = H'  $\cup$  h
10:        end if
11:    end for
12:    H = H  $\cup$  H'
13: end while
14: return H

```

and refine it until complete and consistent concept descriptors are obtained. Once some concept descriptors are discovered, target instances that are deducible by the concept descriptor are removed from the data set – this step is called covering, and the process restarts with the remaining target instances. The algorithm terminates when all the target instances are explained; or the number of uncovered target instances drops below a certain threshold; or when no more concept descriptors can be discovered to model the remaining target instances. Algorithm 1 presents the generic concept discovery process.

ILP-based and graph-based approaches are two competitors in concept discovery. ILP-based approaches have long dominated the research in concept discovery and have been successfully applied in several domains such as engineering (Dolsak & Muggleton, 1992), bioinformatics (Turcotte, Muggleton, & Sternberg, 2001) and environmental sciences (Džeroski, Jacobs, Molina, Moure, Muggleton, & Van Laer, 1998). ILP-based concept discovery systems are classified as bottom-up and top-down. In bottom-up systems, an initial hypothesis, called *bottom clause*, that describes a single positive target instance is constructed and is iteratively generalized to cover as many positive target instances as possible and as few negative target instances as possible. In top-down systems, an overly general initial concept descriptor that models all the target instances is constructed and is iteratively specialized to cover as few negative target examples as possible. Hybrid systems that combine properties of both approaches are also studied in the literature.

Another research direction in concept discovery is based on graphs. Among others, a common problem faced by ILP-based concept discovery systems is the so-called locale plateau problem, where refinement by one literal at a time operators are insufficient to improve rule quality. Richards and Mooney (Richard & Mooney, 1992) proposed a graph pathfinding-based approach, which refines the concept descriptors with multiple literals at a time to solve the local plateau problem. Thence-

forth, several graph-based concept discovery systems have been proposed with successful applications. In literature there exist several studies that compare performance of ILP-based and graph-based concept discovery systems and argue that graph-based systems are competitive to ILP-based ones and might be of more expressive power (Gonzalez, Holder, & Cook, 2000).

In graph-based concept discovery systems relational data is represented as a graph and graph algorithms are utilized to mine the concept descriptors. Graph-based concept discovery systems are classified as substructure-based and pathfinding-based approaches. In substructure-based approaches, it is assumed that concepts should appear as frequent substructures in a graph; hence such substructures are sought. In pathfinding-based approaches, it is assumed that concept descriptors should appear as fixed length paths that originate from target instances and go through similar nodes. There also exist hybrid systems that combine properties of substructure-based and pathfinding-based approaches. Substructure discovery is known to be NP (Yan & Han, 2002) and path finding approaches require extensive path profiling mechanism.

GRAPH-BASED CONCEPT DISCOVERY

Input to graph-based concept discovery systems is a graph representation of the relational data. Graphs are one of the fundamental data structures and data representation frameworks of computer science. A graph, G , consists of non-empty set of *vertices*, V , and a set of *edges*, E . Edges connect two-element subsets of nodes which are called *endpoints* of the edges. G is called directed graph if endpoints are ordered and undirected otherwise. A graph is *labeled* if its vertices or edges or both are assigned specific values.

Graph-based concept discovery systems primarily differ from each other by means of the structure they consider to represent concepts. Other

Table 1. Sample kinship dataset

Target Instances	Background Knowledge	
husband(Marco, Lucia).	father(Marco, Alfonso). father(Marco, Sophia). mother(Lucia, Alfonso). mother(Lucia, Sophia).	brother(Marco, Angela). sister(Lucia, Emilio).

than this, graph-based concept discovery systems also differ from each other by means of data representation, search technique, noise handling mechanism, and concept descriptor evaluation method. In the rest of this section we introduce pioneering works and state-of-the-art studies and discuss how they handle the above listed issues.

One of the earliest works that utilized graphs for concept discovery is Relational Pathfinding (Richard & Mooney, 1992). It is a pathfinding-based approach, where data is represented as an directed labeled graph where vertices represent relation arguments and edges connect arguments whose values form a fact, either a target instance or a background fact, e.g. representation of Table 1 is as in Figure 1. Although it is not clearly stated in the study, Relational Pathfinding allows target instances to be n-ary relations while limiting the background data with unary and binary relations. The system picks random target instance at random, and creates as many vertices as its arguments and marks them as unexpanded. Iteratively, each yet-unexpanded vertex is expanded by adding vertices that represent arguments of a relation where that particular

Figure 1. Most common two data representation formats: attribute-based representation

vertex takes part. Once a path that connects any two arguments of the target instance is established, the path is output as a concept descriptor.

Relational Paths Based Learning (RPBL) (Gao, Zhang, & Huang, 2009a) is pathfinding-based approach where data is labeled directed graph. Vertices represent facts from background data and edges connect those vertices that share an argument of the same type and value, e.g. representation of Table 1 is as in Figure 2. To discover concept descriptors, RBPL picks a number of target instances and constraints the source, s , and target, t , nodes based on them. If t is a target instance of form $t(A, B)$, then s is $T(A, *)$ and t is $p(?, B)$ where p is a relation from the background data. To find paths, RBPL employs breath first search. Once a vertex that matches p is discovered, the path is pinned as a concept descriptor. Similar to Relational Pathfinding algorithm, constants are replaced with variables to obtain the final concept descriptors.

Figure 2. Most common two data representation formats: fact-based representation

In (Gao, Zhang, & Huang, 2009b), RPBL is extended to handle domain theories and discover recursive concept descriptors. Domain theories are intensional definitions of relations. If such definitions are provided, graph is extended by adding new edges that connect vertices that hold for the domain theories. To discover recursive concept descriptors, target instances are also added to the graph. It follows the same search method with RPBL to discover concept descriptors.

Mode Directed Path Finding (MDPF) (Ong, de Castro Dutra, Page, & Costa, 2005) is an application of pathfinding-based concept discovery on bottom clauses. It differs from Relational Pathfinding and RPBL not only by means of working on a bottom clause, but also by employing hypergraph as a representation framework. Each literal in the body of the bottom clause is represented as a vertex in the hypergraph. Edges are created based on the input/output mode declarations among literal arguments. The head literal, i.e. target relation to be learnt, is represented with n distinct vertices, n being the arity of the head literal, which are sources of paths. Initially each path is of length 0 and is associated with a list, L_p , and contains the value of the vertex. Concept discovery method of MDPF is similar to Relational Pathfinding method. Vertices are expanded in breadth-first manner with their related facts, and at end of the each expansion the newly reachable values are added to the list. To find the concept descriptors, Mode Directed Path Finding compares each list against every other list. If any two lists intersect they are merged to form the final concept descriptor.

Another study that works on bottom clauses and makes use of mode declarations is Head Output Connected (HOC) Predicate learning system (Santos, Tamaddoni-Nezhad, & Muggleton, 2009). HOC class of clause is a special case of clauses induced by general pathfinding-based concept discovery systems. A clause $h \leftarrow b_1, b_2, \dots, b_n$ is said to be HOC if and only if (i) input variables for each body literal are either subset of the head input variables or are found in a previous body literal, and (ii) all head output variables are instantiated in

the body. Similar to Mode Directed Path Finding approach, HOC system builds a directed labeled graph from body literals of the bottom clause. It connects the vertices that contain input variables to those that have those input variables as output variables. It employs breadth-first search to find concept descriptors.

Some recent studies extended pathfinding-based approaches to graph databases. A recent study by Abay et al (Abay et al., 2015a) uses Neo4j graph database to mine relational data. Similar to Relational Pathfinding approach, vertices represent literal arguments and edges connect those that form a fact. It follows association rule mining techniques to guide the search and prune the intermediate concept descriptors. Best concept descriptor is selected based on F1 metric. The proposed approach is limited to work on binary relations that do not contain numeric values. The proposed method can infer concept descriptors of HOC class. This work also demonstrates applicability of No-SQL systems on concept discovery. The method is extended in (Abay, Mutlu, & Karagoz, 2015b) to handle n-ary relations and numeric attributes.

SUBDUE (Holder, Cook, & Djoko, 1994) is one of the pioneering works in the substructure-based concept discovery problem. It inputs a labeled, directed multi-graph where arguments are represented as vertices and edges connect arguments that form a valid fact and are labeled after the relation name. Initially, SUBDUE assumes each vertex as a valid substructure. Iteratively, substructures are expanded by one edge in all possible ways. At the end of each expansion, the substructures are evaluated and pruned based on their Minimum Description Length (Barron, Rissanen, & Yu, 1998) value. SUBDUE employs inexact graph match approach to find similar substructures; hence can handle noisy data. SUBDUE does not discover definitions of a specific target relation, but definitions of any concept that is hidden in the data.

SUBDUECL (Gonzalez, Holder, & Cook, 2002) is an extended version of SUBDUE to

discover concept descriptors for a specific target relation. Basically it employs the same data representation framework and core functions of SUBDUE. It differs from SUBDUE in learning and concept descriptor evaluation mechanisms. To evaluate the substructures, it employs set covering function instead of compression. Quality of a substructure is calculated with respect to the number of positive target instances that it does not explain and the negative target instances it explains. It employs constrained beam search and considers only as many substructures as the size of the beam at a time.

Concept Learning From Inference Patterns (CLIP) (Yoshida & Motoda, 1995) is a substructure-based concept discovery system, which utilizes colored, directed graph for data representation. In such a representation, colors encode attributes of a fact. CLIP assumes that each connected pair of vertices is a possible concept descriptor. CLIP employs beam search to find patterns. At each iteration, it finds similar pairs of vertices and replaces them with a new vertex and edges are rearranged, i.e. edges that originate or arrive at the vertices now point to the newly added vertex. CLIP decides the similarity of substructures based on their graph identities. Final concept descriptors are determined based on their compression degree of the original graph.

Graph-based Induction (GBI) (Yoshida, Motoda, & Indurkha, 1994) is another substructure-based concept discovery system. It employs basics of CLIP and discusses what types of problems can be represented as colored graphs. Matsuda, Motoda, Yoshida, & Washio (2002) further extends CLIP to handle self-loops and new pattern evaluation techniques.

In literature there are systems that combine properties of both approaches. One such study is by Mutlu & Karagoz (2013). It is similar to substructure-based approaches as it groups similar vertices and represents them as a single vertex. It is similar to pathfinding-based approaches, as it looks for paths in the compressed graph. It assumes that group of facts are similar if they are

related in the same way, i.e. have same value at the same argument place. To find paths, it follows iterative deepening search. The proposed algorithm restricts facts to be binary relations and can infer HOC type of concept descriptors. Igde, Kavurucu, & Mutlu (2015) extend this work to handle n-ary relations. Both studies evaluate the concept descriptors based on their coverage. Different than all other studies described above, these two systems utilize graphs to guide the search rather than mining.

Although graph-based for concept discovery systems are proposed to solve certain limitations of ILP-based systems, they pose certain problems. Both substructure-based and pathfinding-based approaches are computationally expensive. When compared to each other, SUBDUE distinguishes from other works as it can discover definitions of different relations at a time. CLIP is more tolerable to noise, as it considers substructures similar even they have some distortions. HOC system and MDPF build their search spaces based on a bottom clause, if the bottom clause is built for an improper target instance, the systems may fail to find concept descriptors of high quality. This problem also holds for Relational Pathfinding and RPBL. The hybrid approaches discussed above overcome this problem by considering all the target instances at the same time.

RUNNING EXAMPLE FOR GRAPH-BASED CONCEPT DISCOVERY

In this section we provide a working example for graph-based concept discovery. This is the demonstration of study by (Abay et al., 2015a). The study uses Neo4j database engine to represent relational data and induce concept descriptors. It uses No-SQL technology to retrieve data. The running example is based on the following kinship data set where *elti* is a Turkish kinship. Two women are called *elti* if they are married to two male brothers. In the proposed method, data is represented as directed, labeled graph. Vertices

Table 2. A sample kinship data set

Target Instances	Background Knowledge
elti(ayse, cemile). elti (ayten, ayse). elti (nalan, bedriye). elti (bedriye, nalan).	husband(altan, ayse). wife (cemile, osman). wife(ayse, altan). brother(altan, osman). husband(osman, cemile). wife(nalan, sadullah). husband(ismail, ayten).

represent relation arguments and edges connect nodes that form a relation. Direction of edges implies the semantics of relations, i.e. osman is connected to cemile with an edge labeled husband, which indicates osman is husband of cemile. Graph representation of Table 2 is given in Figure 3.

To induce concept descriptors, the system makes use of Neo4j's path traversal methods and extracts all paths of length less than maximum rule length that originate from an argument of the target relation. Such paths include P1: elti(ayse,cemile); P2: elti(ayse,cemile), wife(ayse,altan), husband(altan,ayse), wife(ayse,altan); P3: elti(ayse,cemile), wife(ayse,altan), brother(osman,altan), husband(osman,cemile). Next, it eliminates all paths of length 1 as such paths are the target instances, i.e. P1, and paths that contain loops, i.e. P2, as revisited nodes do

not add extra information. Following the pruning step, the system replaces constants with variables. As an example, P3 becomes elti(A,B), wife(A,C), brother(C,D), husband(D,B). Finally support and confidence values of all such generalized paths are calculated and those that fall below user-defined thresholds are pruned. To evaluate support and confidence of concept descriptors they are transformed into SQL queries. Support of a concept descriptor is the number of target instances it deduces, and confidence is the number of instances, either from the target relation or background knowledge, it deduces. Generalized version of P3 maps to the following support and confidence queries:

- **Support:** *SELECT COUNT(DISTINCT CONCAT(elti.arg1, elti.arg2)) FROM elti, wife, brother, husband WHERE elti.arg1 = wife.arg1 AND wife.arg2 = brother.arg1 AND brother.arg2 = husband.arg1 and elti.arg2 = husband.arg2*
- **Confidence:** *SELECT COUNT(DISTINCT CONCAT(p1.arg, p2.arg)) FROM person as p1, person as p2, wife, brother, husband WHERE p1.arg = elti.arg1 AND p2.arg = husband.arg2 AND wife.arg2 = brother.arg1 AND brother.arg2 = husband.arg1*

Figure 3. Graph representation of sample kinship data set
Abay et al., 2015a.

Authors report in their study that graph construction takes 1 second for a data set with 224 instances and 2 seconds for a data set with 744 instances. When compared to ILP-based concept discovery system called CRIS, their study discovers concept descriptors with higher accuracy for some data sets. The running time of the system is also reported as feasible. These findings in coverage and running time comply with the findings of (Gonzales et al, 2000).

FUTURE RESEARCH DIRECTIONS

To improve running time of graph-based concept discovery systems there are several options. Parallelization poses several alternatives to improve running time of such systems. Graphs constructed to represent relational data may be very large. For example for PTE data set is represented by a graph that contains 22268 vertices and 22863 edges (Cai, Jonyer, & Paprzycki, 2005). Parallelization in graph-based concept discovery may be achieved in several manners. The first option is to distribute the data among several workers, each building its graph, and all searching for definitions of a specific target instances in their own graph. Another option is to distribute the entire data among the workers, each worker building the whole graph, and searching definitions of several target instances in parallel. Although there are several studies in literature that address such problems, there are still open problems such as reasonable load balancing, and communication cost.

Heuristics such as one proposed in (Mutlu, Karagoz, & Kavurucu, 2013) may be investigated to further improve efficiency of graph-based concept discovery systems where the order of the target instances effects the number of concept descriptors discovered and the running time of the system. Selecting the most promising target

instance to start the search may greatly improve the outcome of the concept discovery systems.

Introduction of fuzziness in such systems is also another research direction. As such systems prune possible concept descriptors based on metrics such as support, confidence and compression rate, pruning based on crisp thresholds may lead to loss of valuable concept descriptors.

Although some arguments of relations that take part in a concept descriptor are free variables, in the-state-of-the-art systems, relations take part in the concept descriptors in their full definitions. Systems may be modified to induce concept descriptors based on relation arguments rather than relations. By this way, concept definitions will not contain irrelevant information.

Functionalities of graph databases may be integrated into graph-based concept discovery systems. Such systems provide mechanism for exact and optional match of pattern and data. By such functionalities noisy data may better be analyzed.

CONCLUSION

In this chapter, we introduce concept discovery problem and compare several graph-based approaches by means of data representation, search method and concept evaluation technique. Although the problem has been researched for almost three decades now and its theoretical foundations are well established, it still has certain problems. To overcome the scalability issues, methods based on parallelization, heuristic development may further be investigated. To handle noisy data, fuzzy set oriented approaches may be investigated. In addition, new technologies such as graph databases deserve more attention for their possible applicability in concept discovery. Another possible research direction may include investigation of different models for concept descriptor representation.

KEY TERMS AND DEFINITIONS

Breadth-First Search: Breadth-first search is a graph traversal method where firstly neighbor nodes are visited rather than sibling nodes.

Concept Discovery: Given a set of fact, concept discovery is the problem of learning definitions of a fact in terms of other facts.

Covering: Learning is an iterative process and at each rules possible with high accuracy and low coverage are induced. Removing learnt instances from the training set is called covering.

Depth-First Search: Depth first search is a graph traversal method where a branch is traversed as deep as possible without visiting any neighbor nodes.

Inductive Logic Programming: Given a set of observations, Inductive Logic Programming is concerned inducing general patterns that explain the observations.

Healthcare Data Analysis in the Internet of Things Era

George Tzanis

Aristotle University of Thessaloniki, Greece

INTRODUCTION

Health care advances are taking place rapidly all over the world. The newest medical discoveries and higher quality of medical practice have guided to serious improvements in human health and well-being. Life expectancy has been considerably increasing, leading to an aging population with different needs and desires. Moreover, world population has been rising exponentially, challenging the effectiveness of healthcare systems. New tests, procedures, and medicines have made medical care increasingly expensive, forcing the restraint of costs even while overall effectiveness improves (Vasanth & Sbert, 2012). Nowadays, prevention and early detection of disease signs as well as quality of life are becoming the points of focus more than ever before. Furthermore, personalized medicine is deemed particularly important and promises better disease treatment for each individual. Patients are becoming better-informed, want to know more about their health and their treatment, and demand to be involved in decision-making regarding their health.

All the aforementioned trends and changes have revealed the necessity to adopt a different model of health care. The modern healthcare delivery system should be more patient-centric, rather than career-centric, in order to deal effectively with the new challenges. Such a healthcare system should be organized in a layered structure (Pang, 2013) as shown in Figure 1. For example, the lower layer should comprise the single person and the higher one the hospital. Between these two terminal layers one can find the home and community layers. The lowest layer (person) is characterized by the

lowest labor intensity and operational cost, as well as the highest frequency of usage for chronic disease and lowest frequency of usage for acute disease. In contrast, the highest layer (hospital) has the highest labor intensity and operational cost, as well as the highest frequency of usage for acute disease and lowest for chronic disease.

The delivery model of health care is now standing at the starting point of its way to transform from the traditional hospital-centric to the modern home-centric/person-centric approach. The Internet of Things with its pervasive, personalized, and ubiquitous character can guide health care through this way. Many relevant concepts have been introduced to describe the future healthcare model powered by emerging information and communication technologies. Various terms, such as connected health, health Internet of Things (Health-IoT), pervasive healthcare (pHelath), ubiquitous healthcare (uHealth), mobile healthcare (mHealth), electrical healthcare (eHealth), telehealth, telemedicine, etc., have been utilized in order to express the plethora of these new concepts (Pang, 2013; Pawar et al., 2012; Rose et al., 2015). All these new concepts include, more or less, the fundamental aspects of the home-centric/person-centric healthcare model.

This article presents the concept of the Internet of Things as applied in health care discussing the benefits and opportunities as well as the posed obstacles and challenges. The article focuses on the basic strategies for analyzing healthcare data generated by the Internet of Things enabled devices and describes the current status, the major challenges, and the future trends of this revolutionary field.

Figure 1. The layered structure of a modern healthcare system

BACKGROUND

According to the definition provided by the telecommunication standardization sector of the International Telecommunication Union (ITU-T Recommendations, 2012), the Internet of Things (IoT) is “a global infrastructure for the information society, enabling advanced services by interconnecting (physical and virtual) things based on existing and evolving interoperable information and communication technologies”. With regard to the IoT, the term “thing” is defined as “an object of the physical world (physical thing) or the information world (virtual thing), which is capable of being identified and integrated into communication networks”. Exploiting various capabilities, concerning identification, data capture, processing, communication, etc., the IoT uses any “thing” to offer any service to any application domain. At the same time IoT has to abide by the requirements for security and privacy (ITU-T Recommendations, 2012).

Undoubtedly the IoT is the future of technology, with societal implications as well, that can make everyday life more efficient. The IoT can be recognized as the second digital revolution (The Government Office for Science, 2014), given that the first one was the World Wide Web, which connected people around the world establishing a global community. The IoT is built on the basis

of the World Wide Web extending its benefits and opportunities, but poses new big challenges. It is expected to greatly integrate leading technologies, such as technologies related to advanced machine-to-machine communication, autonomic networking, data mining and decision-making, security and privacy protection, as well as cloud computing, with technologies for advanced sensing and actuation. As shown in Figure 2, the IoT adds the dimension “any thing communication” to information and communication technologies (ICTs), which already provide “any time” and “any place” communication.

Among the plethora of application domains that can benefit by the utilization of the IoT, health care is one of the most important. Figure 3 presents the most popular IoT applications according to the study of IoT Analytics for Q3/2016. The popularity ranking of the IoT applications was based on 640 actual enterprise IoT projects not including any consumer IoT projects such as wearable devices, smart home or hobby projects.

Vilamovska et al. (2009) have classified IoT applications, in particular RFID applications, in healthcare across two axes:

- **IoT Enabling Functions:** These are four key and mutually exclusive functions concerning assets, staff and patients.
 - Tracking.

- Identification and authentication.
- Automatic data collection and transfer.
- Sensing.
- **Healthcare Applications:** These are the four most promising areas of applications
 - Patient safety and quality of care.
 - Pharmaceutical application (not including supply chain and counterfeit drug issues).

Figure 2. The new dimension (any thing communication) introduced with the Internet of Things
Source: ITU-T Recommendations, 2012.

Figure 3. The most popular Internet of Things applications; valid for Q3/2016
Source: IoT Analytics, 2016.

- Management of devices, supplies and biological material.
- Patient and healthcare provider support and management.

Examples of healthcare applications for each enabling function are presented as a four-by-four matrix in Table 1.

HEALTHCARE DATA ANALYSIS

Healthcare data analysis and analytics can support the basic goals of a healthcare system. The objectives that can be addressed through healthcare data analysis have been classified into three major axes by Cortada, et al. (2012) as presented in the following lines:

- **Improvement of Clinical Effectiveness and Patient Satisfaction:**
 - Improvement of clinical quality of care.

- Improvement of patient safety and reduction of medical errors.
- Improvement of wellness, prevention and disease management.
- Better understanding of physician profiles and clinical performance.
- Improvement of patient satisfaction, acquisition and retention.

- **Improvement of Operational Effectiveness:**

- Reduction of costs and increase in efficiency.
- Optimization of network management.
- Improvement of pay for performance and accountability.
- Increase in operating speed and adaptability.

- **Improvement of Financial and Administrative Performance:**

- Increase in revenue and return on investment (ROI).
- Improvement of utilization.
- Optimization of supply chain and human capital management.

Table 1. Preliminary list of the most promising areas for RFID deployment in healthcare

	Patient Safety/Quality of Care	Pharmaceutical Application	Management of Devices, Supplies and Biological Material	Patient and Healthcare Personnel Support/Management
Tracking	Tracking vulnerable patients (dementia) Tracking patient location to account for patient time during treatment	Easy recall of products	Prevention of leftins during surgical procedures Equipment tracking (ensure hygiene, compliance, regular maintenance, fast spotting when needed)	Personnel tracking to improve workflow and reduce patient waiting times in emergency room
Identification and authentication	Mother–newborn accurate matching	Auto ID-enabled medication administration system	Maintenance of real-time clinical information associated with patient within a hospital	Patient identification to reduce incidents harmful to patients (wrong drug, dose, time, procedure)
Automatic data collection and transfer	Use of portable devices for care coordination.	Tracking pharmaceutical inventories	Inventory management for better use of staff time and faster care delivery	IoT-supported automated care, pathways, procedures audit, and management
Sensing	Patient vital signs to trigger alerts for medical personnel, and remote monitoring at patient's home	Patient compliance with prescribed medication treatment (in and out-patient)	Blood bags equipped with temperature sensors in hospital to ensure cold chain and efficacy	Personnel and asset tracking to ensure infection control (nosocomial infections)

Source: Vilamovska et al., 2009.

- Improvement of risk management and regulatory compliance.
- Reduction of fraud and abuse.

Data Mining

Data mining emerged in order to cope with the challenges that traditional data analysis techniques were facing up when dealing with large amounts of data. Moreover, these data often have a lot of peculiarities (e.g. missing values, noise, etc.). More specifically, data mining is the main step in the process of Knowledge Discovery in Databases or KDD Process (Figure 4). Knowledge Discovery in Databases is defined as the non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data (Fayyad et al., 1996). However, the term “data mining” is very often used to describe the whole KDD Process. Although the core of the process is the data mining step, where a data mining algorithm is applied in order to extract the patterns from data, the pre-processing and post-processing phases are very important too and contribute sensibly to the quality of the extracted knowledge. The pre-processing phase usually includes the selection of an appropriate portion of data, the cleansing of the selected data, as well as the transformation of data in more appropriate representations. The

post-processing phase deals with the management of the produced patterns and models and focuses on the evaluation and interpretation of data mining results.

Data mining, in practice, has the following two “high-level” primary goals (Fayyad et al., 1996):

- **Prediction:** Involves the use of some fields (variables) in a database to predict unknown or future values of other variables of interest.
- **Description:** Focuses on finding human-interpretable patterns describing the data.

Prediction and description are not equivalently important for every data mining application. In the context of Knowledge Discovery in Databases, description tends to be more important than prediction. In contrast, machine learning and pattern recognition applications, usually favor prediction as the primary goal. Prediction and description are achieved by using various data mining tasks, the most common of which are presented in Table 2 (Dunham, 2002). Depending on the nature of the data and the desired knowledge there is a large variety of algorithms for each task. A thorough review of the application of data mining in health care can be found in (Koh & Tan, 2005; Yoo et al., 2012).

Figure 4. The KDD process
Source: Revised from Tzani (2012).

Table 2. Most common data mining tasks

Tasks for Description	Tasks for Prediction
• Association Rules Mining: Extracts rules expressing relationships among variables of data. Similar task is <i>sequence analysis</i> where relationships are based on time. • Clustering: Groups data, so that data in the same group (cluster) are more similar to each other than to those in other groups. • Summarization: Maps data into subsets with associated simple descriptions. Also called <i>characterization</i> or <i>generalization</i>.	• Classification: Maps data into predefined classes, using a model that is constructed on data with known class mappings. • Regression: Maps data into a real valued prediction variable, using a model constructed on data with known mappings. • Time Series Analysis: Examines the sequence of events where an event is determined by one or more of the preceding events.

Big Data Challenges

Although data mining provides the means to deal efficiently with large amounts of, usually, peculiar data, healthcare data analysis in the Internet of Things era is far from an uncomplicated task. The term “big data” is very popular nowadays and is used to describe the explosively extended collections of data, which carry significantly more peculiarities. The popularity of the “big data” concept is signified by the fact that a lot of challenges regarding the management and analysis of big data have been raising, whereas the benefits and opportunities ensuing from the exploitation of these data seem to be manifold and very attractive. The conventional data analysis tools, including machine learning and data mining, are not efficient anymore and have to be scaled in order to deal with the obstacles posed by the big data paradigm.

The basic peculiarities that figure the challenging character of big data are described by the “5-V’s”. Laney (2001) introduced the term “3-V’s” in big data community, namely volume, variety, and velocity. However, since then there have been proposed even more “V’s”, but two of them, variability and value, are the most popular (Fan & Bifet, 2012). These “5-V’s” are described in the following lines (Fan & Bifet, 2012; Fayyad, 2012):

- **Volume:** The volume of the data has been growing rapidly, more than ever before, providing challenges in loading, processing, and transferring.

- **Velocity:** The velocity of data streams that arrive continuously and need to be analyzed pose challenging real-time constraints.
- **Variety:** There are many different types of data (e.g. text, sensor data, images, audio, video, graph), various degrees of structure in data (structured, semi-structured, unstructured), and often different types and structures of data are mixed.
- **Variability:** The structure of the data as well as the way users are willing to interpret these data usually changes with time providing extra data and knowledge management challenges.
- **Value:** The value refers to the quality of the extracted knowledge that may give the ability of making better decisions and answering more questions.

SOLUTIONS AND RECOMMENDATIONS

Health care, like many other areas, follows the big data paradigm presented above. Healthcare data are becoming available at rapid rates and as the exploitation of the IoT infrastructure grows, data management and data analysis becomes even more challenging. Subsequently, individual hardware units are not any more adequate to satisfy the computational requirements for managing and analyzing these data. New algorithmic approaches with increased scalability and efficiency and infrastructures that make use of the computational power of multiple hardware units, such as distributed and cloud computing, are deemed necessary.

The prevalent trend in dealing with the big data storm is the concept of cloud computing. According to NIST definition (Mell & Grance 2011), “cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interaction”.

Cloud services can be grouped in three main groups (Mell & Grance 2011):

- **Software as a Service (SaaS):** The capability provided to the consumer is to use the provider’s applications running on a cloud infrastructure. The applications are accessible from various client devices through either a thin client interface, such as a web browser or a program interface.
- **Platform as a Service (PaaS):** The capability provided to the consumer is to deploy onto the cloud infrastructure consumer-created or acquired applications created using programming languages, libraries, services, and tools supported by the provider.
- **Infrastructure as a Service (IaaS):** The capability provided to the consumer is to provision processing, storage, networks, and other fundamental computing resources where the consumer is able to deploy and run arbitrary software, which can include operating systems and applications.

There are various cloud deployment models that have their own benefits and drawbacks. The selection of a proper model depends on the specific application domain. These deployment models are (Mell & Grance 2011; Botta et. al, 2016):

- **Private Cloud:** Provisioned for exclusive use by a single organization and may be owned, managed, and operated by the organization, a third party, or a combination of them.

- **Community Cloud:** Provisioned for exclusive use by a specific community of consumers from organizations that have shared concerns and may be owned, managed, and operated by some of the organizations in the community, a third party, or a combination of them.
- **Public Cloud:** Provisioned for open use by the general public and may be owned, managed, and operated by a business, academic, government organization, or a combination of them.
- **Hybrid Cloud:** Composed of two or more distinct cloud infrastructures (private, community, or public) that remain unique entities, but are bound together by standardized or proprietary technology that enables data and application portability.
- **Virtual Private Cloud:** Exploits virtual private network (VPN) technologies for allowing organizations to setup required network settings (e.g. topology, security, etc.).

Cloud computing and the IoT are two novel and promising concepts of technology that have been evolving independently. Although they are different, they have complementary characteristics as shown in Table 3. Due to this complementarity many researchers have been thinking about the possible benefits of the fusion of these two technologies proposing approaches that integrate

Table 3. Complementary characteristics of cloud computing and IoT

	Internet of Things	Cloud Computing
Displacement	Pervasive	Centralized
Reachability	Limited	Ubiquitous
Components	Real world “things”	Virtual resources
Computational capabilities	Limited	Virtually unlimited
Role of the Internet	Point of convergence	Means for delivering services
Big data	Source	Means to manage

Source: Botta et. al, 2016.

cloud computing and the IoT (Cloud-IoT) in various application domains (Alhakbaniet al., 2014; Botta et. al, 2016; Diaz et al., 2016; Gomes et al., 2014). The benefits are mutual for these two technologies. The IoT can exploit the virtually unlimited capabilities and resources of cloud computing to compensate its technological constraints and cloud computing can extend its scope to deal with real world “things” in a more distributed and dynamic manner, delivering novel services in a large number of real life cases.

The adoption of the innovative infrastructures of Cloud computing and IoT in health care has lead to a paradigm shift in healthcare data management and analysis. The traditional standalone, local, offline data analysis model has been replaced by a more dynamic, global and regularly online data management and analysis paradigm. Cloud-IoT is able to simplify healthcare processes, enhance the quality of medical services by enabling cooperation among interconnected entities. For example Ambient Assisted Living (AAL) aims at easing the daily lives of people with disabilities and chronic diseases (Botta et. al, 2016). Cloud-IoT may supply many innovative services, such as patients’ vital data collection through sensor networks, data transfer to medical centers’ Cloud infrastructures, management, sharing and ubiquitous access of Electronic Healthcare Records (EHR), etc (Botta et. al, 2016, Kuo, 2011). Moreover, Cloud allows better confrontation with common challenges of healthcare domain such as security, privacy, and reliability, by enhancing medical data security as well as service availability and redundancy. Cloud enables the execution of secure healthcare services, overcoming the issue of limited computational capacity and power. It provides the means for a flexible and scalable storage and processing in order to efficiently perform online and offline analyses of data.

FUTURE RESEARCH DIRECTIONS

The introduction of the Cloud-IoT paradigm in the healthcare domain can offer numerous benefits and opportunities that will considerably improve

the quality of healthcare services in the era of big data. This is a recently emerged research area and is expected to receive the focus of the future research efforts. Although the aims for storage and management of large amounts of data in the IoT infrastructure can be provided by the integration of the IoT and cloud computing, there are still open issues concerning verification, normalization, filtering and analysis of the IoT data (Diaz et al., 2016). The lack of open standards, the large diversity of technologies involved in the IoT, as well as the huge amounts of data require novel techniques to improve and optimize such integration problems.

From a broader perspective, the basic challenges that concern Cloud-IoT healthcare applications and should be addressed in the future are presented below (Atzori et al., 2010; Botta et. al, 2016; Rose et al., 2015):

- **Privacy and Security:** These challenges may concern the lack of trust in the cloud service providers, the lack of knowledge about the physical location of data, the exposure of the distributed system to possible attacks and vulnerabilities, etc.
- **Legal and Social Issues:** The legal challenges are important depending on the specific application and different international laws. Moreover, social issues become extremely important, since humans are becoming the source of sensor data.
- **Large Scale:** This relates to applications which include a very large number of “things”, distributed across very wide areas.
- **Reliability:** This arises with mission-critical applications.
- **Performance:** This concerns applications having specific performance and Quality of Service requirements at multiple levels (communication, computation, storage).
- **Heterogeneity:** This refers to heterogeneity of devices, platforms, operating systems, services, etc.

CONCLUSION

Undoubtedly the IoT is the future of technology, which can provide manifold benefits to health care. However, the posed challenges are also great. Concerning the analysis of healthcare data, various tools have been introduced to deal efficiently with the large volumes as well as the various peculiarities of data (e.g. missing values, noise, etc.). The most popular representative of these modern tools is data mining, or the KDD process, strictly speaking. Although the KDD process has provided a lot of solutions, these techniques have to be scaled in order to deal with the new challenges posed by the big data paradigm. Cloud computing is the modern infrastructure that can provide the means to efficiently manage big data. Both, cloud computing and the IoT are very promising concepts of technology and their complementary characteristics assure that their integration, Cloud-IoT, will provide a great potential of applications. The introduction of the Cloud-IoT paradigm in the healthcare domain can offer manifold benefits and opportunities that will considerably improve the quality of health care.

KEY TERMS AND DEFINITIONS

Ambient Intelligence: The discipline aims to bring intelligence to everyday environments making them sensitive and responsive to the presence of people in a non-intrusive way and with minimal explicit interaction.

Artificial Intelligence: The area of computer science that studies the construction of computer programs that can imitate human cognitive abilities and present behaviors indistinguishable from human behavior.

Internet of Medical Things (IoMT): A global infrastructure consisting of the collection of medical devices and applications that are interconnected through information and communication technologies.

Machine Learning: The field of study that deals with the construction of algorithms that can learn from data and make predictions on data.

Radio Frequency Identification (RFID): The technology that incorporates the use of electromagnetic fields to uniquely identify and track a tagged object.

Ubiquitous Computing: The discipline aims to bring computing anywhere and anytime in any object. It is also called pervasive computing.

Wi-Fi: The technology that allows electronic devices to connect to a wireless local area network (WLAN) and Internet using radio waves.

Wireless Sensor Network (WSN): The network of spatially distributed autonomous sensors which monitor physical or environmental conditions and cooperatively pass their data through the network to a main location.

N-Tuple Algebra as a Unifying System to Process Data and Knowledge

Alexander Yakovlevich Fridman

Institute for Informatics and Mathematical Modelling, Kola Science Centre of RAS, Russia

BACKGROUND

Theory of relations is mostly used in databases modeled by means of relational algebra (Codd, 1971). However, many diverse and (at first sight) different mathematical objects, namely graphs, semantic networks, expert rules, predicates, logical formulas, etc., can be expressed as relations. Relational algebra does not provide sufficient techniques to deal with such models and structures.

Modern intelligence systems comprise two types of dissimilar objects, namely databases (DBs) and knowledge bases (KBs). Their structures are quite distinct since they exploit fundamentally different theoretical approaches. Nowadays, data structures (numbers, vectors, graphs, networks, texts, etc.) correspond to algebraic methods (Wirth, 1976). As for KBs, their basic models (predicates, frames, semantic networks, rules and so on) are designed on the basis of declarative approach (Russel & Norvig, 2003). This incompatibility results in significantly different programming systems and structures for DBs and KBs, and consequently, in big difficulties to integrate a DB and a KB within one software system.

Conventional attempts to do so relate to the declarative approach mostly. The model of deductive databases (Ullman, 1989; Ceri, Gotlob, & Tanca, 1990) gives an example of such attempts. It is grounded on a modification of Prolog language designed within the declarative approach.

Conversely, some shortcomings inhere in this approach. One of the major problems is in the

necessity to reduce many tasks of logical analysis to satisfiability checks for a certain logical formula, this check being able to return only two possible answers (“yes” or “no”). Such a reduction is not simple. Moreover, it is unrealizable in cases when one needs to not only receive a binary answer but also to estimate the value of some parameters in the formal system or to assess the structure and/or number of objects that satisfy the given conditions.

To model and analyze modified reasoning (that is reasoning with hypotheses and abductive conclusions), many authors propose usage of non-classical logics (Russel & Norvig, 2003). However, such logics often have no interpretation or their interpretations do not correspond to semantics of the objects to be modeled. In the authors’ opinion, there are some reasons to suppose that problems in modeling modified reasoning within classical logic result from features of the declarative approach rather than from drawbacks of classical logic.

Algebraic approach to logical modeling can be originated from Aristotle’s syllogistics and Boole’s logical matrices, in more recent times only Arkady Zakrevskij (for instance, see (Zakrevskij & Gavrilov, 1969)) investigated set-theoretical approach to logic and proposed a programming language LYaPAS (Logical Language for Representation of Synthesis Algorithms) oriented toward programming of synthesis algorithms for finite-state and discrete devices. However, this language does not provide any means for logical inference.

To overcome the mentioned and other problems, the mathematical model of relational algebra was generalized by the authors to a more universal system for processing n -ary relations called n -tuple algebra (Kulik, 1995, 2007; Kulik, Fridman, & Zuenko, 2013, 2015).

N-TUPLE ALGEBRA: BASICS AND FEATURES

N -tuple algebra is a mathematical system to deal with arbitrary n -ary relations. In NTA, such relations can be expressed as four types of structures called *NTA objects*. Every NTA object is immersed into a certain space of *attributes*. Names of NTA objects contain an identifier followed by a sequence of attributes names in square brackets; these attributes determine the *relation diagram* in which the NTA object is defined. For example, $R[XYZ]$ denotes an NTA object defined within the space of attributes

$X \times Y \times Z$ that is $R[XYZ] \subseteq X \times Y \times Z$.

From the mathematical point of view, NTA is an *algebraic system* $A = \langle A, O, R \rangle$, where *carrier* A is an arbitrary totality of relations expressed as NTA objects; O is a set of *operations* comprising *algebra of sets' operations* (union, intersection, complement) and *operations on attributes* (see below); R is a set of verified *relations* between NTA objects, namely equality and inclusion. This algebraic system is proved to be complete (i.e. all operations and checks of relations are feasible for any totalities of NTA objects).

NTA objects defined on the same relation diagram are called *homotypic* ones. NTA objects contain n -tuples of sets and provide a condensed representation of n -ary relations. In NTA, *elementary n -tuples* correspond to n -tuples of elements in ordinary relations. For instance, the record $T[XYZ] = (a, b, c)$ means that T is an elementary n -tuple where $a \in X, b \in Y, c \in Z$.

NTA objects look like matrices having subsets of corresponding attributes (*components*) rather than elements as their cells. The totality of NTA components includes two *dummy components*. They are: the *complete component* $*$ that equals to the whole domain (i.e. the range of values) of the corresponding attribute in the relation diagram and the *empty component* $\emptyset$ that equals to the empty set and models the complement of the component $*$.

NTA admits 4 types of NTA objects, namely C - n -tuples and C -systems, D - n -tuples and D -systems.

A C - n -tuple is an n -tuple of components defined in a certain relation diagram, denoted within square brackets and interpreted as the set of elementary n -tuple contained in the Cartesian product of its components. For example, the right part of the formula $R[XYZ] = [A * C]$ expresses a C - n -tuple that can be transformed into an ordinary n -ary relation by calculating the Cartesian product $A \times * \times C$ where $A \subseteq X, * = Y$ is a complete component placed to the position of the attribute Y , and $C \subseteq Z$.

A C -system is a set of homotypic C - n -tuples that are denoted as a matrix in square brackets. As an example, the C -system

$$Q[XYZ] = \begin{bmatrix} A_1 & B_1 & * \\ * & B_2 & C_2 \end{bmatrix}$$

can be reduced to a set of elementary n -tuples calculated by formula

$$Q[XYZ] = (A_1 \times B_1 \times Z) \cup (X \times B_2 \times C_2).$$

A D - n -tuple expresses a structure that can be interpreted, in particular, as a complement of a certain C - n -tuple. Suppose, the C - n -tuple

$$R[XYZ] = [A \ B \ C]$$

is given. Its complement equals to the difference of C - n -tuples

$$[X \ Y \ Z] \setminus [A \ B \ C] = (X \times Y \times Z) \setminus (A \times B \times C).$$

The formula of difference for two Cartesian products is well known, for the given example it equals:

$$\begin{aligned} (X \times Y \times Z) \setminus (A \times B \times C) &= \\ ((X \setminus A) \times Y \times Z) &= \\ \cup (X \times (Y \setminus B) \times Z) &= \\ \cup (X \times Y \times (Z \setminus C)) &= \end{aligned}$$

In NTA terms, the right part of this formula can be denoted as the C -system

$$\overline{R} [XYZ] = \begin{bmatrix} \overline{A} & * & * \\ * & \overline{B} & * \\ * & * & \overline{C} \end{bmatrix}$$

where $\overline{A}$, $\overline{B}$, $\overline{C}$ mean complements of the components A , B , C to the domains of corresponding attributes.

The square C -systems like $\overline{R} [XYZ]$ where all nondiagonal cells contain complete components are called *diagonal C -systems*. Without any loss of information, they can be written as an n -tuple of the diagonal components. To distinguish them from C - n -tuples in NTA, we use reversed square brackets instead of regular ones. So, for the given example

$$\overline{R} [XYZ] =] \overline{A} \ \overline{B} \ \overline{C} [.$$

A D -system is a structure that consists of a set of homotypic D - n -tuples and equals to their intersection. The list of D - n -tuples in a D -system is limited with reversed square brackets.

NTA laws are based on the laws of algebra of sets and properties of the Cartesian product. Let us introduce main NTA relationships.

Suppose two homotypic C - n -tuples

$$P = [P_1 P_2 \dots P_n] \text{ and } Q = [Q_1 Q_2 \dots Q_n]$$

be given. Then:

1. $P \subseteq Q$, if and only if $P_i \subseteq Q_i$ for all $i = 1, 2, \dots, n$;
2. $P \cap Q = [P_1 \cap Q_1 \ P_2 \cap Q_2 \ \dots \ P_n \cap Q_n]$. Moreover, if for any i $P_i \cap Q_i = \emptyset$, then $P \cap Q = \emptyset$;
3. $P \cup Q = \begin{bmatrix} P_1 & P_2 & \dots & P_n \\ Q_1 & Q_2 & \dots & Q_n \end{bmatrix} \subseteq [P_1 \cup Q_1 \ P_2 \cup Q_2 \ \dots \ P_n \cup Q_n]$;
4. Equality $P \cup Q = [P_1 \cup Q_1 \ P_2 \cup Q_2 \ \dots \ P_n \cup Q_n]$ is possible in two cases only:
 - a. $P \subseteq Q$ or $Q \subseteq P$;
 - b. $P_i = Q_i$ for all corresponding pairs of components except one pair;
5. $\overline{P} =] \overline{P}_1 \ \overline{P}_2 \ \dots \ \overline{P}_n [.$

Numerous examples of representing different data and knowledge structures as NTA objects are given in our references listed below. Due to size limits of this paper, we give only one example of how to apply NTA structures for logical analysis. This example uses variables that contain more than two values, which makes it possible to analyze the logic models that go beyond the propositional calculus. Suppose we want to find the object, which is in one of three rooms. At the same time, you may not enter one of the rooms (there is a danger), and one of the rooms is empty. There are two following clues:

1. The first room is not dangerous, the second is not empty;
2. The third room is not dangerous, the second is not empty.

We also know that one of the clues is true, the other one is false.

Let us denote A the statement “the room contains the desired object”, B – “the room is empty” and C – “the room is dangerous”. Attributes names will be equal to the names of the rooms R_1, R_2, R_3 . Each of these rooms corresponds to one of situations from the permitted situations set $\{A, B, C\}$.

The given conditions can be expressed by C - n -tuples as follows.

$$T_1[R_1R_2R_3] = [\{A, B\} \{A, C\} *]; 2) T_2[R_1R_2R_3] = [* \{A, C\} \{A, B\}].$$

To solve the problem, it is necessary to consider two possible cases: 1) The first clue is true, and the second is false; 2) The first clue is false, and the second is true.

Let us consider the first case. If T_2 is false, its negation

$$\overline{T_2} =]\emptyset \{B\} \{C\}[$$

is true. To find a solution, one needs to find the intersection of the true conditions:

$$T_1 \cap \overline{T_2} = [\{A, B\} \{A, C\} *] \cap]\emptyset \{B\} \{C\}[=$$

$$[\{A, B\} \{A, C\} *] \cap \begin{bmatrix} * & \{B\} & * \\ * & * & \{C\} \end{bmatrix} = [\{A, B\} \{A, C\} \{C\}].$$

The resulting C - n -tuple contains 4 possible placement options (one can find this by calculating the Cartesian product of $\{A, B\} \times \{A, C\} \times \{C\}$). However, according to the conditions of the problem, the correct placement must have different situations in different rooms, i.e. the only placement (B, A, C) is correct. It means that the desired object is located in the second room. Similar results can be obtained when testing the second case.

The above listed relationships provide proving all the rest NTA laws, which assisted in composing algorithms of NTA operations and checks of equality and inclusion for any homotypic NTA objects.

To implement NTA operations and checks for any (possibly non-homotypic) NTA objects, it is necessary to define generalized operations and relations based on some operations upon attributes.

NTA: GENERALIZED OPERATIONS AND OPERATIONS UPON ATTRIBUTES

Let us introduce operations on attributes first.

- *Renaming of attributes* is used when it is necessary to substitute variables, particularly, in algorithms for calculating transitive closure of a graph.
- *Transposition of attributes* is an operation that swaps columns in an NTA object's matrix and respectively changes the order of attributes in the relation diagram.
- *Elimination of an attribute* ($-Attr$) is done in the following way: a column is removed from an NTA object, and the corresponding attribute is removed from the relation diagram.
- *Addition of a dummy attribute* ($+Attr$) is done when the added attribute is not yet present in the relation diagram of an NTA object. This operation adds the name of a new attribute into the relation diagram and simultaneously adds a new column with dummy components into the corresponding place; dummy components “*” are added into C - n -tuples and C -systems, and dummy components “ $\emptyset$ ” are added into D - n -tuples and D -systems.

By defining the operation $+Attr$, we have eliminated the restriction in the theory of relations stating that algebra-of-sets laws are only applicable to the relations defined upon the same Cartesian product.

The operation $+Attr$ is often used to reduce some different-type NTA objects to the same relation diagram by adding the missed attributes. Then one can perform all necessary operations and checks by means of standard NTA algorithms.

Considering this, we have introduced *generalized operations* ($\cap_G, \cup_G$). They differ from

corresponding operations of algebra of sets by the only feature: NTA objects are reduced to the same relation diagram before execution of these operations, which are semantically equal to logical connectives: disjunction and conjunction correspondingly. *Generalized relations* ($\subseteq_G$ and $=_G$) are defined similarly.

Algebra of n -ary relations with the mentioned generalized operations and relations is proved to be isomorphic to the ordinary algebra of sets.

NTA: CORRESPONDENCE WITH PROPOSITIONAL AND PREDICATE CALCULI

A C - n -tuple corresponds to *conjunction* of unary predicates with different variables. For example, in predicate calculus the C - n -tuple

$$P[XYZ] = [P_1 P_2 P_3]$$

where

$$P_1 \subseteq X; P_2 \subseteq Y; P_3 \subseteq Z$$

models the logical formula

$$H = P_1(x) \wedge P_2(y) \wedge P_3(z)$$

where X , Y and Z are ranges of values for the variables x , y and z .

A D - n -tuple corresponds to *disjunction* of unary predicates with different variables. For instance, the D - n -tuple

$$Q[XYZ] = [Q_1 \quad Q_2 \quad Q_3]$$

corresponds to the logical formula

$$F_2(x, y, z) = Q_1(x) \vee Q_2(y) \vee Q_3(z).$$

C -systems are convenient for representing *disjunctive normal forms* (DNFs) of unary predicates,

and D -systems model *conjunctive normal forms* (CNFs) of unary predicates.

An elementary n -tuple that is a part of a non-empty NTA object corresponds to a *satisfying substitution* in a logical formula.

An empty NTA object corresponds to an *identically false formula*.

An NTA object $P[XY...Z]$ that equals to $X \times Y \times \dots \times Z$ corresponds to a *valid formula*, or a *tautology*.

A non-empty NTA object models a *satisfiable formula*.

Now let us consider quantifiers in NTA.

Adding a dummy attribute to a C - n -tuple or a C -system corresponds to the *rule of generalization* in predicate calculus. For example, if an NTA object

$$G[XZ] = \begin{bmatrix} \{a, c\} & * \\ \{a, c, d\} & \{b, c\} \end{bmatrix}$$

corresponds to a formula $F(x, z)$ of this calculus, by adding a dummy attribute Y into this NTA object we get an NTA object

$$G_1[XYZ] = +Y(G[XZ]) = \begin{bmatrix} \{a, c\} & * & * \\ \{a, c, d\} & * & \{b, c\} \end{bmatrix}$$

which models the formula $\forall y F(x, z)$.

Elimination of an attribute from a C -system (D -system) is proved to be equivalent to the universal (existential) quantification on this attribute. Thus, if an NTA object $R[XYZ]$ models a formula $F(x, y, z)$, then $-Y(R[XYZ])$ corresponds to $\exists y F(x, y, z)$, if $R[XYZ]$ is a C -system, and to $\forall y F(x, y, z)$, if $R[XYZ]$ is a D -system.

To obtain NTA representations for formulas of propositional calculus containing logical variables $x_1, x_2, \dots, x_n$, it is enough to assign every variable x_i with the attribute $X_i = \{0, 1\}$. Then the dummy component $*$ corresponds to the set $\{0, 1\}$, literal x_i corresponds to $\{1\}$, and its nega-

tion $\neg x_i$ corresponds to $\{0\}$. For example, the formula

$$F(x, y, z) = (x \vee \neg z) \wedge (\neg y \vee z)$$

corresponds to the D -system

$$R[XYZ] = \begin{bmatrix} \{1\} & \emptyset & \{0\} \\ \emptyset & \{1\} & \{0\} \end{bmatrix}.$$

The negation of this formula

$$\neg F(x, y, z) = (\neg x \wedge z) \vee (y \wedge \neg z)$$

is modeled by the C -system

$$\overline{R}[XYZ] = \begin{bmatrix} \{0\} & * & \{1\} \\ * & \{0\} & \{1\} \end{bmatrix}.$$

It is easy to see that relations between C -objects (C - n -tuples and C -systems) and D -objects (D - n -tuples and D -systems) are in accordance with de Morgan's laws of duality. Due to this fact, they are called *alternative classes*.

All NTA objects model scopes of truth for their corresponding logical formulas. In NTA, attribute domains can be any arbitrary sets that are not necessarily equal to each other. Thus, NTA structures model formulas of *many-sorted predicate calculus*.

This paper does not consider matters of complexity in detail; they are described in (Kulik, 1995). It was proved that *computational complexity of algorithms on NTA structures fully corresponds to computational complexity of algorithms solving problems on logical structures*. However, the matrix properties of NTA objects allowed us to find some special cases that are solvable in polynomial time only (Kulik, 1995). Moreover, such structure is good to reduce computational complexity of NTA operations by their effective parallelization (Kulik & Fridman, 2014).

LOGICAL INFERENCE IN NTA

Theoretical principles of NTA provide solving the following problems of deductive analysis:

1. Problem of correctness check for an alleged consequence B from the given premises A_i .
2. *Problem of deriving possible consequences from the given premises A_i* considering certain semantical constraints, for instance, presence of given variables or their combinations in a consequence, deriving a consequence with the minimal number of significant variables, etc.

Unlike other logical systems that solve such problems by using inference rules with hardly optimized order of their implementation, NTA solves these problems by means of certain standard algorithms. To do so, we transform classical logic' formulas expressing premises and consequences into NTA objects and subject these objects to generalized operations and checks of equality ($=_G$) or inclusion ($\subseteq_G$). The transition to the algebraic representation becomes clearer, if you consider that NTA objects model scopes of truth for logical formulas. Then the correctness proof for an alleged consequence B from the premises A_i requires for calculating generalized intersections and checking the following generalized inclusion:

$$(A_1 \cap_G \dots \cap_G A_n) \subseteq_G B \quad (1)$$

Considering (1), the problem to derive possible consequences $\{B_j\}$ from the given premises A_i can be solved in NTA by using the relation that must be true for every B_j : $A \subseteq B_j$, where $A = A_1 \cap_G \dots \cap_G A_n$. Thus, any correct consequence from premises A_i can be modeled by an NTA object representing a superset of A . To find such objects, NTA proposes several techniques. One of them is *calculating projections of an NTA object*. This operation is simple if A is a C -system. Then the projection can be found by operation $-Attr$. It is easy to prove that any projection of an NTA

object models its superset. This technique allows checking the possibility to obtain consequences containing certain variables.

The relationship (1) allowed for an NTA definition of the *minimal consequence* from axioms $A_1, A_2, \dots, A_n$ that equals to the NTA object

$$A = A_1 \cap_G A_2 \cap_G \dots \cap_G A_n.$$

This consequence is the minimal one as it is proved to satisfy the two following statements:

1. Any strict subset of A is not derivable from the axioms $A_1, A_2, \dots, A_n$;
2. If S is an arbitrary NTA object from the proper universe, the NTA object $A \cup S$ is derivable from the axioms $A_1, A_2, \dots, A_n$.

In some kinds of reasoning models, a consequence B is considered a suitable solution of an inference task if this consequence contains fewer variables than the minimal consequence A (such a consequence can be found by using the above-introduced Technique 1). This decrease in number of variables in the formula $B = A \cup S$ results from transformation of some variables in the formula A into dummy ones after adding S to it.

NTA: MODELS OF PLAUSIBLE REASONING

Some difficulties in applying propositional and predicate calculi to analysis of plausible reasoning arose from the fact that mathematical logic recognizes inconsistency of a reasoning system (a theory) if and only if both a corollary and its negation follow from the same premises. Conversely, commonsense reasoning recognize inference of contrary corollaries (for instance, both statements “All A are B ” and “No A are B ”) as a definite criterion of inconsistency for a knowledge system though they are not formally contradictory.

In order to eliminate this and other discrepancies between formal logic and natural deduction, we propose a concept of “*collision*” in our logical analysis system (Kulik, 1995).

Unlike a logical contradiction, collisions can have opposite interpretations in different cases. For example, within one system the equality $R = \emptyset$ means the absence of an object that is necessary for existence of the system, and in another system (where the object R is not necessary) this equality specifies a status of this object. The first case requires for changing the premises while the second case provides a new useful knowledge.

Collisions mostly occur during defeasible reasoning when new knowledge or a hypothesis is included into the logical system. Collisions indicate violations of some formal rules or restrictions providing consistency of this system.

By using collisions, NTA allows for a formal definition of hypotheses. Let us suppose that a system of premises expressed as NTA objects $A_1, A_2, \dots, A_n$ is given and the NTA object $A = A_1 \cap_G A_2 \cap_G \dots \cap_G A_n$ is calculated.

Then a certain formula H is called a *hypothesis* under the following conditions:

1. $A \subseteq_G H$ is false. Otherwise, H is a consequence according to (1).
2. The hypothesis is correct, if the object $H \cap_G A$ contains no collisions.

The first condition can be expressed in other way: $A \setminus_G H \neq \emptyset$. The second condition assumes that the hypothesis is a premise or an axiom.

Usually, forming and checking of hypotheses accompany other analysis methods for defeasible reasoning. Below, we will describe usage of hypotheses in searching for abductive conclusions.

Abduction is forming of an explanatory hypothesis when one knows some of premises and an estimated consequence confirmed with facts or reasonable arguments, but a formal check does not infer it from the given premises. For example, abduction is used during diagnostics.

Let us now formally define abduction.

If B is an estimated consequence from the premises

$$A = A_1 \cap_G A_2 \cap_G \dots \cap_G A_n$$

and the statement $A \subseteq_G B$ is known to be false, then a formula H is an *admissible abductive conclusion* when the two following conditions are met:

1. H is a hypothesis (i.e. $A \subseteq_G H$ is false) and $H \cap_G A$ is not empty;
2. $(H \cap_G A) \subseteq_G B$, that is adding H into the system of premises results in deducibility of the estimated consequence B .

Considering the above definitions, we propose a search algorithm for abductive conclusions.

Examples of using this algorithm in (Kulik, Zuenko, & Fridman, 2015).

MEASURES IN NTA

NTA structures consist of sets of n -tuples being Cartesian products in essence. A measure (a probabilistic measure in particular) can be easily calculated for a Cartesian product, that is why NTA structures can be readily immersed into a space with a measure. For instance, if measures of a C - n -tuple' components are known, the measure of the C - n -tuple itself equals to the product of these measures. It is not that easy to calculate a measure for a C -system since intersections of some its elements can be not empty. That is why we have developed algorithms to transform any NTA structure to an orthogonal C -system that has no overlapping pairs of C - n -tuples (Kulik, 2007). Then its measure equals to the sum of the measures for the C - n -tuples comprising it.

Let us introduce two possible ways to use metric properties of NTA objects.

The first way proposes the number of elementary n -tuples as a measure based on the following regularity. Let a C - n -tuple be given in a space of attributes $P = [P_1 \ P_2 \ \dots \ P_n]$ with a finite number of their values. Then the power $|P_i|$ of every component P_i is a finite number as well, and the power (that is the number of elementary n -tuples) of the C - n -tuple P equals to $|P| = |P_1| \cdot |P_2| \cdot \dots \cdot |P_n|$. By using our orthogonalization algorithm, it is possible to count the power of every NTA object having finite sets as its components.

The second way to use metric properties of NTA objects is suitable for implementation of the logic-probabilistic analysis (LPA) for systems modeled by logical functions (Kulik, 2007).

This approach corresponds to the *direct problem* of LPA, when the probability of a complex event is calculated for given probabilities of elementary events. In the *inverse problem*, it is necessary to calculate probabilities of elementary events based on the data about probabilities of certain complex events. After this, one can calculate the probabilities of other complex events. Problems solved in probabilistic logic are of this type (Kulik, 2007; Nilsson, 1986).

Let us analyze an example from (Nilsson, 1986).

Assume that a totality of the given events is defined by formulas A and $A \supset B$ of propositional calculus, besides, $p(A) = p_1$ and $p(A \supset B) = p_2$. It is necessary to estimate the probability $p(B)$ for the event B .

We will solve this problem by means of NTA. Here are two logical variables A and B , which model elementary events as well. Let us suppose probabilities of these events equal to $p(A)$ and $p(B)$ correspondingly. The statement of this problem gives $p(A) = p_1$. Now we will express the given formulas in NTA structures within the universe

$$\{0, 1\}^2: A = [\{1\} *];$$

$$B = [* \{1\}];$$

$$A \supset B = \overline{A} \vee B =]\{0\} \{1\}[= \begin{bmatrix} \{0\} & * \\ \{1\} & \{1\} \end{bmatrix}$$

(here the D - n -tuple modeling the formula $A \supset B$ is transformed into an orthogonal C -system).

Then the probabilistic formulas for the events A and $A \supset B$ are as follows:

$$P(A) = p_1; P(A \supset B) = (1 - p(A)) + p(A)p(B) = p_2.$$

So, we have got a system of two equations:

$$p(A) = p_1;$$

$$(1 - p(A)) + p(A)p(B) = p_2$$

that allows to easily conclude

$$p(B) = \frac{p_1 + p_2 - 1}{p_1}.$$

This is the precise result for this problem while N. Nilsson (1986) gives an interval estimate for this result, namely

$$p_2 + p_1 - 1 \leq p(B) \leq p_2.$$

FUTURE RESEARCH DIRECTIONS

In the authors' opinion regarding NTA development, future research ought to include the following directions: context-oriented database (knowledge base) management systems; additional means of immersing NTA structures into measure spaces and assigning NTA objects with quantitative features; modeling dynamic intelligent systems (Vinogradov, Zhilyakova, & Osipov, 2002) within the situational approach; applications NTA methods to smart electromechanical systems (SEMS) (Kulik & Fridman, 2016).

CONCLUSION

This paper introduces a new mathematical instrument, n -tuple algebra (NTA), implementing the algebraic approach to the general theory of n -ary relations. Unlike relational algebra and theory of binary relations, NTA uses Cartesian product of sets rather than elementary n -tuples as a basic structure and is based on some generalized operations and relations. They provide logical processing of relations with different relation diagrams; these methods have no analogies in convenient theories. NTA belongs to the class of Boolean algebras. It is proved to be isomorphic to algebra of sets and supports unified implementation of various data/knowledge structures typical for artificial intelligence and many techniques of their semantic and logical analyses. Matrix properties of NTA objects allow to decrease complexity of intellectual procedures for some new structural and statistical classes of CNFs with polynomially identifiable satisfiability as well as by efficient parallelization of logical inference algorithms. NTA structures can be readily immersed into spaces with a measure. In particular, some new solutions were found for the direct and inverse problems of the logic-probabilistic analysis.

ACKNOWLEDGMENT

The authors would like to thank the Russian Foundation for Basic Researches (grants 14-07-00256, 14-07-00257, 15-07-04760, 15-07-02757, 16-29-04424, and 16-29-12901) for partial funding of this research.

KEY TERMS AND DEFINITIONS

C-n-Tuple: An n -tuple of components defined in a certain relation diagram; domain of each component is a subset of the domain of the corresponding attribute.

Collisions: Situations occurring during defeasible reasoning when some new knowledge (hypothesis) is inputted. Such situations can be recognized as violations of some formally expressed rules and/or limitations which control consistency and meaning content of a logical system.

C-System: A set of homotypic C - n -tuples that are denoted as a matrix in square brackets and equal to the intersection of these C - n -tuples. The rows of this matrix are C - n -tuples.

D - n -Tuple: An n -tuple of components enclosed in reversed square brackets and equal to a diagonal C -system with the same diagonal components.

D -System: A set of homotypic D - n -tuples equal to the intersection of these D - n -tuples.

Generalized Operations and Relations: They differ from similar operations and relations of algebra of sets by the only feature: NTA objects (operands) are reduced to the same relation diagram before executing these operations or checking the relations.

N-Tuple Algebra: An algebraic system whose support is an arbitrary set of n -ary relations expressed by specific structures, namely, C - n -tuple, C -system, D - n -tuple, and D -system. These structures provide a compact expression for sets of elementary n -tuples.

A Proposed Framework for Incorporating Big-Data Technology in National Crisis Management Center

Magdy M. Kabeil

Al-Yamamah University, Saudi Arabia

Ahmad M. Kabil

University of Wisconsin – Whitewater, USA

INTRODUCTION

Along with the major development in many aspects of life, the current millennium has brought for several countries significant crises of different kinds and various degrees (Farazmand, 2014). The increasing jeopardizing to crises calls for a transformational change in countries' capability to manage crises. Crises may be natural or manmade. It may be on organizational or national levels.

The main measure of merit in crisis management is the ability to allocate all relevant capabilities to be the most effective on the right points at the right times over all crisis phases (Kabil & Kabeil, 2014 & 2011). On such measure, the national crisis management currently faces two critical challenges. The first is the high pace of crisis scenario relative to the corresponding management decision cycles. The second critical challenge is the large scale of volume, variety, and velocity of pertinent data.

However, if we record a crisis scenario on a video recorder and replay it in slow motion, we will see the crisis features very similar to a regular problem's features. On the other side, if a National Crisis Management Center (NCMC) can provide the decision makers with the capabilities that allow them to feel, recognize, abstract, comprehend, analyze, and decide faster, then the crisis management processes will be as manageable as the regular problem management processes.

The Big-Data Technology (BDT) as an accurate representation of real life could be used in both ways, to understand the real life and to control it. Fast cycles of understanding and controlling real life situations are the key functions of national crisis management.

This chapter presents a framework for incorporating BDT in traditional conceptual designs of NCMC. The updated conceptual design is validated using the Analytical Hierarchy Process (AHP) and the Quality Function Deployment (QFD) technique. The conceptual design provides a system that is responsive to decision makers' need in developing their own crisis management centers. The initial stages and steps required for implementing the conceptual design in a country are given.

BACKGROUND

The quality of decision, such as any other engineering product, is built from the very beginning all through the decision processing cycle (Davern et al. 2008). The generic decision cycle in crisis management context starts with data gathering that is processed further to higher levels of information, knowledge, intelligence, wisdom, and decision. Decisions are implemented through a Command, Control, Communication, Computer, Intelligence, Surveillance, and Reconnaissance

(C4ISR) System to move a real-world-situation to be more suitable for the next decision or action (Kabil & Kabeil 2014). The model has been updated in response to the evolution of BDT as depicted in Figure 1.

There are several definitions of the term “Big-Data.” Perhaps the most popular definition is based upon the IBM’s differentiation that is based on 3 attributes of the 3 V words, Volume, Variety, and Velocity (IBM, 2016; Sagioglu & Sinanc 2013). Leverage the traditional “Data” concepts and technologies to “Big-Data” ones affects all higher levels of the model.

One of the most important implications of using BDT in crisis management is crisis crowdsourcing. Developing more new technologies capable of collecting, communicating and disseminating individuals information on macro scales has led to more forms of crowdsourcing in crisis management (Kahl et al., 2012). Recent research efforts on crisis crowdsourcing address new issues around using information and communication technologies to engage and coordinate with the wider public during crisis management. The Crisis Crowdsourcing Framework defined by Liu (2014) uses the same traditional information-gathering six dimensions of why, who, what, when, where, and how to identify the interaction mechanisms

that should be considered by designers of crisis crowdsourcing systems.

On the “Where” dimension, the geographically oriented Big-Data could be provided using Location-Based Services (LBS). The LBS could be used to locate living entities or objects across telecommunication networks. Several technologies are utilized by LBS for knowing where an information device is geographically located. Examples of technologies used for LBS are the Global Positioning Satellites (GPS), Assisted Global Positioning Satellites (AGPS), Cell Identification (Cell ID), Broadband Satellite Network (BSN), Radio Frequency Identification (RFID), and Near-Field Communication (NFC).

Ma (2011) proposes a real-time LBS that can enable hospitals treating victims during a disaster relief scenario. The author analyzes how a network of hospitals can use such LBS to handle medical aspects of disaster relief. He suggests a framework for following available hospitals capability, allocating victims among hospitals, tracking patients who are in-transit from one hospital to another, and developing strong collaborative network of personnel across all areas of the hospitals service. The emerging technology of smart watches with embedded sensors to recognize objects and forearm gestures expands the use of such appli-

Figure 1. From data to decision

cations in full integration with RFID and NFC technologies.

Remote sensing is a valuable source of spatial information in the event of a natural disaster, and its utility has been proven on many occasions around the world (Kumar et al., 2014). Joyce et al. (2009) address the use of remote sensing as a rapid-response data source and present a number of data types and image processing techniques along with airborne and satellite technologies used to map and monitor a crisis theater.

Big-Data is used for finding insights in new types of content to answer questions that were previously considered beyond the reach (LaValle, et.al, 2011). Che et al. (2013) consider Big-Data as greatly expanded assets to human and they argue that all what we need then is to develop the right tools for overcoming the scalability challenge of Big-Data and developing Big-Data Analytics.

Baboo and Kumar (2013) present an overview of the next generation data warehouse architecture that is based upon Big-Data for better business insights. The proposed architecture consists of three tiers, which are the extracting of Big-Data from multiple sources, storing and cleansing, and the analytical reporting. Within such architecture, a typical Big-Data processing framework relies on cluster computers with a high-performance computing platforms. The data processing tasks are being deployed by running parallel programming tools on a large number of computing nodes. A single data processing task is split into many small tasks each of which is running on one or multiple computing nodes (Wu et al., 2014). Che et al. (2013) review several attempts that have been made on exploiting massive parallel processing architectures for Big-Data Analytics.

The Big-Data Analytics helps analyzing online data about all relevant individuals and objects rather than measuring data from a sample of population. Measuring data from a sample usually carries two types of statistical errors known as “Type I” and “Type II” (Stevens, 2012). In crisis management context, “Type I” error is to neglect an individual or a group in population who should

be considered. And, “Type II” error is to consider an individual or a group who is not relevant to the case. Additional shortage of measuring data from a sample is the lack of concurrency and timeliness due to the period of conducting a sampling process.

The Big-Data paradigm provides a vast variety of new kinds of priors and estimation techniques to inform all sorts of decisions. The impact on the economy has been referred to as “the new oil” (Kolb & Kolb, 2013: p. 10). Its impact on the social sciences can be compared with the impact of the invention of the telescope for astronomy and the invention of the microscope for biology (Nature Editorial, 2008). The presented study can help investigating its impact on crisis management on the national level.

INCORPORATING BIG-DATA TECHNOLOGIES IN NCMC

Kabil and Kabeil (2014) suggest a generic conceptual design of National Crisis Management Center (NCMC) that covers initial requirements and basic functions for managing crises on the national level of a country. The conceptual design consists of four functional units, which are the Intelligence Unit, the Design & Operations Unit, the Choice Unit, and the Integration & Display Unit.

The Intelligence Unit includes 7 modules, which are Monitoring Module, Database Module, Planned Communication Module, Ad-Hoc Communication Module, Reconnaissance Module, Assumptions & Forecasting Module, and Validation & Reasoning Module. The Design & Operations Unit includes 6 modules, which are the Analysis & Knowledge Management Module, Modeling & Simulation Module, Operations Module, Social & Media Module, Political Module, and Government Departments Module. Both the Choice Unit and the Integration & Display Unit had not been decomposed into modules at this time.

The generic conceptual design of NCMC depicted above has been updated to include emerging BDTs. Keeping the same basic structure of the

center, the functions of existing modules have been updated and several new modules have been added. The updating of the NCMC's conceptual design is illustrated in Figure 2.

The Intelligence Unit has been updated by adding a new element of Sensors & Cell Devices to the Monitoring & Measuring Module and by replacing the Database Module with the Big-Data Storage & Cloud Module. The functions of the remaining four modules of the Intelligence Unit

have been updated under the same names. Also, the functions of the six modules of the Design & Operations Unit have been updated under the same names. The Choice Unit has been decomposed into six modules and the Integration & Display Unit has been also decomposed into six modules.

The updated unites and modules of the NCMC's conceptual design are defined in the following items.

Figure 2. Updated conceptual design of NCMC

NCMC-1: Intelligence Unit

The information relevant to the decision situation is gathered and maintained by the intelligence unit all through the crisis life cycle. The unit includes seven updated modules as defined in the following items:

NCMC-1.1: Monitoring & Measuring Module, which supports the production, dissemination, and display of crisis theater data. It consists of five nodes that can create, receive, edit, transmit, and store video clips as well as images, graphics, voice, text data, and measuring signals.

NCMC-1.2: Big-Data Storage & Cloud Module, which includes an integrated collection of NCMC's core data corresponding to the needs of expected crises.

NCMC-1.3: Planned Communication Module, which is responsible for building and managing a network of distributed data sources belonging to several organizations and government departments.

NCMC-1.4: Ad-Hoc Communication Module, which is responsible for developing an index of data sources of different specialties and deploying an ad-hoc network of communication with them.

NCMC-1.5: Reconnaissance Module, which is responsible for conducting physical information- capturing activities of strategic or operational significance.

NCMC-1.6: Assumptions & Forecasting Module, which is responsible for filling gaps of data in the decision structure and conducting forecasting activities including meteorological forecasts, prediction of decision consequences, and early warning capabilities.

NCMC-1.7: Validation & Reasoning Module, which is responsible for checking the validity of data collected through the Intelligence Unit's modules and conducting data reasoning that allows crisis management team to

rely on information as facts, even though they have not specifically verified it in a physical manner.

NCMC-2: Design and Operations Unit

The main responsibility of the Design & Operations Unit is to develop enough alternatives for decision choices. The unit includes six updated modules as defined in the following items:

NCMC-2.1: Analysis & Knowledge Management Module, which is responsible for dealing with both explicit and tacit knowledge. The module is in full coordination with the Big-Data Storage & Cloud Module (NCMC-1.2) in the Intelligence Unit for Big-Data mining and extracting knowledge about behavior of individuals, groups, concepts, and objects.

NCMC-2.2: Modeling & Simulation Module, which is responsible for developing and maintaining the model-base of the NCMC.

NCMC-2.3: Operations & Robotics Module, which is responsible for conducting military actions in crisis context. Diverse military operations in crises context are a part of one or more of Direct Action, Psychological Operation, Civil Affairs, Information Operations and Hacking, and Robots Operations. Despite the fact that each one of these missions uses its own DSS-C4ISR system, interfacing these systems to the crisis decision structure is the duty of the Operations & Robotics Unit in the NCMC.

NCMC-2.4: Social & Media Module, which is responsible for communicating with the community and media at large.

NCMC-2.5: Political Module, which is responsible for handling the foreign affairs and international relations issue in crisis context. The module includes BDT in multilingual capability of communication in continuous accumulated processes.

NCMC-2.6: Government Departments Module, which is responsible for communicating and coordinating with other ministries and administrations according to their specialties in crisis management.

NCMC-3: Choice Unit

The Choice Unit is responsible for developing a preferences structure of group decision makers in crisis context (Limayem et al., 2006). The updated structure of the Choice Unit includes six modules as defined in the following items:

NCMC-3.1: Crowdsourcing Module, which is responsible for conducting public participation in crisis management. Crowdsourcing is an emerging, large-scale arena for Internet-mediated interaction that has implications for both informal and formal responses (Liu, 2014). With a focus on persistent citizen communications, the module follows their spatial arrangements, and how the emerging information serve different crisis management functions (Palen & Liu 2007).

NCMC-3.2: Group Wisdom Module, which is responsible for incorporating and integrating the wisdom of decision makers in the choosing process (Adkins et al. 2002).

NCMC-3.3: AHP Module, which is used for organizing the complexity of decision structure, determining the internal and total priorities of alternatives, forecasting about next move of crisis actors, allocating resources, selecting the most relevant cases to retrieve for investigation, integrating qualitative factors with quantitative factors in decision structure, and evaluating the ethical responsibilities in inverse decision support cases (Kabil 2012).

NCMC-3.4: Scenario & Sensitivity Analysis Module, which is responsible for studying consequences of decisions in each scenario, for checking the sensitivity of a decision to any changes may arise in decision parameters, and for checking the validity of data

received from the Assumptions & Forecasting Module of the Intelligence Unit.

NCMC-3.5: Artificial Intelligence & Expert Systems Module, which is responsible for improving the effectiveness and efficiency of decision-making processes using several Artificial Intelligence & Expert Systems methods (Khalil et al. 2012).

NCMC-3.6: Time Management & Tasks Synchronization Module, which is responsible for monitoring, controlling and adjusting the pace of decision cycle over crisis events.

NCMC-4: Integration and Display Unit

The Integration & Display Unit is responsible for integrating all unites and modules of the NCMC and facilitating its team to access transparently the internal and external components of the system (Huang et al., 2002). The updated structure of the Integration & Display Unit includes six modules as defined in the following items:

NCMC-4.1: Team Interface Module, which is responsible for creating and providing interface that minimizes the time of team comprehension. The module is able to combine several displays in a single dynamic presentation and to supply the displays being generated with various interactive facilities such as zoom, pan, rotate, focus, query, mark, filter, or follow a hyperlink.

NCMC-4.2: Domain Ontology Module, which is responsible for integrating the different ontologies into a new one and for overcoming the diversity of information sources as well as the diversity of information users.

NCMC-4.3: Geo-Positioning & Visualization Module, which is responsible for effective preparation, organization, and representation of Big-Data on intelligent maps suitable for anticipated recipients within the time constraints (Andrienko & Andrienko, 2007).

NCMC-4.4: Deployable Wireless Networks Module, which is responsible for administrating a rapidly deployable broadband wireless communications system for crisis management and emergency response.

NCMC-4.5: Logging & Archiving Module, which is responsible for logging and archiving data that are typically performed on a cyclic basis.

NCMC-4.6: Administration & Security Module, which is responsible for managing a role-based access control and security system. An integrated security mechanism is used to optimize security protocols and mechanisms of various heterogeneous wireless networks in NCMC.

CHECKING THE VALIDITY OF CONCEPTUAL DESIGN

The exercise suggested in this study for testing validity of the updated conceptual design of the NCMC is to recall the W3C's definition of critical steps in crisis response ontologies and to define the requirements for decision support throughout the crisis phases. Based upon the definition of such requirements, a model of QFD is developed to

test the capability of the NCMC to provide these types of support (Kabeil, 2009).

The World Wide Web Consortium (W3C, 2016) represents the noticeable effort in the way of building crisis response ontologies and getting the benefits of semantic web services. According to the W3C's definition, crisis response management should consider 14 critical steps that are included in the first 14 requirements in Table 1. To support decision making and planning, additional knowledge about the actors and types of resources and infrastructure should be considered. So, in addition to the W3C's definition, the table includes more requirements that are common for crisis management scenarios.

The crisis management requirements from the NCMC to handle the crisis are listed with their relative priorities using the AHP. The table includes all requirements in 25 rows along with the Weight and Relative Weight Percent.

The evaluation of the conceptual design modules is conducted using the QFD technique (Kabeil, 2010). The set of crisis requirements and their priorities are used as inputs to the QFD model. The core of QFD is called the House of Quality "HoQ" (Sankaran et.al., 2008) as depicted in Figure 3.

Figure 3. House of quality

Table 1. Priorities of crisis management requirements

RN	% Rel. Weight	Weight (1-5)	Requirements
1	4.2%	5	Once crisis is widely anticipated, sharing of data describing response and resource characteristics are needed.
2	4.2%	5	As the crisis unfolds gathering of data on its scope and emerging effects.
3	4.2%	5	As the response begins, gathering of data on its outages and missing links and matching with relief capacity.
4	4.2%	5	As the response by first responders is overwhelmed, sharing relief requests to prioritize relieving the first responders who are most overloaded or tired.
5	4.2%	5	As the relief unfolds gathering and integrating data from all responders to build a common baseline map of the situation and facilitate probes and first attempts at proactive data gathering.
6	4.2%	5	Characterizing problem states as chaotic (no baseline and no reliable map), complex (changing too fast to identify causes, requires probes) or manageable.
7	4.2%	5	Rapidly deploying compatible information and communication systems to local authorities and institutions capable of dealing with the manageable situations.
8	4.2%	5	Calling for expert review of action proposals to limit/contain chaotic situations, and mass peer review of probes that better define complex ones, with intent to limit the unanticipated side effects of management decisions.
9	4.2%	5	Comparing predicted to measured effects of interventions within 48-72 hours.
10	4.2%	5	Identifying situations which are not improving and calling for more options or more resources.
11	4.2%	5	Helping experienced response teams to move on to the more complex situation by facilitating rapid handoff and just-in-time training of those less experienced.
12	4.2%	5	Guiding recovery and reconstruction efforts by identifying those outages or problems that most inhibit the resilience networks and outside relief efforts.
13	4.2%	5	Guiding resilience efforts by identifying which prevention and anticipation options (e.g. evacuation) could have prevented the most morbidity or loss of life-sustaining infrastructure.
14	4.2%	5	Passing off all data gathered in the disaster to the appropriate authority after the crisis passes, updating databases of vulnerable persons and places.
15	3.3%	4	Locating an individual, facility, vehicle, or object on a map.
16	3.3%	4	Searching for an individual on the map based on her/his profile.
17	4.2%	5	Receiving an emergency request from an individual with her/his location.
18	4.2%	5	Viewing the location of emergency requests on the map.
19	4.2%	5	Disseminating notifications and alerts to each concerned individual.
20	3.3%	4	Storing, maintaining and updating each individual profile and a list of her/his relatives and friends with their current location.
21	2.5%	3	Keeping historical Big-Data of the entire case for analysis and research.
22	4.2%	5	Insuring availability of the system
23	4.2%	5	Insuring security of the system
24	4.2%	5	System user being able to setup and manage the system.
25	4.2%	5	System admin being able to setup and manage the system.
		120	Total Scores

The HoQ matrix correlates requirements “what” to design modules “how” using symbols of “strongly related,” “moderately related,” “weakly related,” or “not related.” The internal relationships between design modules are identified in the upper part of the HoQ matrix. The row score of design

modules is the sum of the product between the relative weights of the integrated requirements and the correlations between requirements and modules as partially depicted in Figure 4.

The output of the HoQ matrix is summarized in Table 2. The relative weights (%) of the NCMC

Figure 4. HoQ of the NCMC

Table 2. Relative weight percent of the NCMC modules

NCMC-4.6	4.1
NCMC-4.5	3.3
NCMC-4.4	2.5
NCMC-4.3	9.5
NCMC-4.2	3.6
NCMC-4.1	5.1
NCMC-3.6	4.0
NCMC-3.5	0.9
NCMC-3.4	3.9
NCMC-3.3	4.2
NCMC-3.2	2.6
NCMC-3.1	6.6
NCMC-2.6	2.6
NCMC-2.5	0.5
NCMC-2.4	2.5
NCMC-2.3	2.1
NCMC-2.2	4.6
NCMC-2.1	3.3
NCMC-1.7	2.2
NCMC-1.6	2.6
NCMC-1.5	5.0
NCMC-1.4	3.2
NCMC-1.3	1.9
NCMC-1.2	11.0
NCMC-1.1	8.2

Cloud module (NCMC-1.2), the Geo-Positioning & Visualization module (NCMC-4.3), and the Monitoring & Measuring Module (NCMC-1.1).

IMPLEMENTATION AND FURTHER RESEARCH DIRECTIONS

Basic modules of NCMIS are developed as a conceptual design, which provides a general foundation for the detailed design and implementation of an application. The conceptual design provides a system that is flexible and responsive to decision makers' need in developing their own crisis management centers. The initial stages of the implementation of NCMC in a country consist of the establishment of facilities and staffs to carry out the basic functions of the center. Once an initial allocation of resources has been made and the functions of the system have been established in an operating condition, the major task in the development of the system involves integrating the various and widespread strategic information activities already existing in the country to the center.

The steps required for implementing the conceptual design of NCMC in a country are:

1. Defining the expected crises in the country and the probability of occurrence of each using historical approach, Delphi method, among other forecasting techniques.
2. Determining the weight of each crisis using the expected monetary value as the probability of occurrence times the value of crisis' consequences.
3. Determining the relative weight of each crisis using the normalization method.
4. Defining the list of requirements for each expected crisis.
5. Based on pairwise comparisons, a composite weight and relative priority are calculated for each item of requirements of each crisis using the AHP.

6. Determining the set of integrated requirements as the union of all requirements of all expected crisis of the country along with the total relative weight of each item in the set using the AHP as depicted in Figure 5.
7. Using the set of Integrated Requirements and their total relative weights as inputs to the HoQ matrix. The outputs of the matrix are the relative weights (%) of the NCMC modules that each component contributes in the implemented design.
8. Establishing other functions of the system in an operating condition.

The future research will be focusing on testing the proposed model in different contexts of country infrastructure and with different scenarios of crisis.

CONCLUSION

The national crisis management currently faces two critical challenges. The first is the high pace of crisis scenario relative to the corresponding

management decision cycles. The second critical challenge is the large scale of volume, variety, and velocity of pertinent data. Incorporating emerging BDT in the design of NCMC is the proposed solution in this study.

Basic modules of updated NCMC are presented as a conceptual design, which provides a general foundation for the detailed design and implementation of an application. The validation of the proposed conceptual design is conducted on a testing-case based upon the W3C's definition of crisis response ontology. The relative percentage of the total score that each module contributes in the conceptual design is evaluated using the QFD technique. The results show that each requirement of national crisis is supported by a set of integrated modules in a balanced way. The modules of the highest contribution in the conceptual design are the modules most related to BDT.

The conceptual design provides a system that is flexible and responsive to decision makers' need in developing their own crisis management centers. The initial stages of the implementation of NCMC in a country and main steps required

Figure 5. Example of integrated requirements with the relative weight of each

for implementing the conceptual design are given. By combining the conceptual design with a test of internal validity and steps of implementation, the study has provided useful information to build upon.

KEY TERMS AND DEFINITIONS

Analytical Hierarchy Process: A technique for pairwise comparisons using judgements of experts to derive priority scales.

Big-Data Analytics: The systematic use of Big-Data and related business insights developed through applied analytical disciplines to drive fact-based decision-making.

Big-Data Technology: A high-resolution representation of real life in such a way that all movements, activities, thoughts, conversations, relations, feelings could be tracked, recorded and processed almost online.

Crisis: A time of danger when important decisions must be developed, communicated and implemented.

Crowdsourcing: The process of obtaining knowledge support by soliciting contributions from a large group of people, especially from an online community.

Location-Based Service: A technology used to locate living entities or objects across telecommunication networks.

National Crisis: A situation or time at which a nation faces intense difficulty, uncertainty, danger or serious threat to people and national systems and organizations and a need for non-routine rules and procedures emerge accompanied with urgency.

Near-Field Communication: A form of short-range wireless communication where the antenna used is much smaller than the wavelength of the carrier signal.

Quality Function Deployment: A technique correlates the design modules to common national crisis management requirements and translates them into specific plans to produce products to meet those needs.

Radio Frequency Identification: A generic term for technologies that use radio waves to automatically identify entities, whatever inanimate, movable, or live.

D

Quality Evaluation for Evolving Conceptual Database Design

Elvira Immacolata Locuratolo
CNR ISTI, Italy

INTRODUCTION

Research at boundary between *information systems* and *software development* is important for today's technology; (Buragga & Zaman, 2013). Before creating an information system, the business and organizational domain in which the information system is used must be represented. This representation, called *conceptual model*, is a critical point for the success of the information system development.

Model-driven engineering is an approach to software development that separates the specification of the system functionalities from its implementation on a particular platform. Models are the primary artifacts of software engineering. Two main categories of *mappings* between models are distinguished:

- Vertical mapping, relating system models at different abstraction levels;
- Horizontal mapping, relating models at the same abstraction level.

The requirements for engineering information modeling enclose complex objects, data exchange, data sharing, web based applications, imprecision uncertainty, and knowledge management. Techniques, such as web and artificial Intelligence, have been introduced in industrial applications.

Databases and Database systems play a main role in supporting data management and in implementing engineering information. Conceptual database design is defined by approaches to *mapping* from conceptual to logical database models (Elmasri & Navathe, 2015). Algorithms of

conceptual database graph partitioning (Locuratolo & Rabitti, 1998; Spagnolo, 2000), originally introduced as algorithms of mapping from semantic data models to object database systems, have been also exploited as techniques for constructive conceptual database design (Locuratolo, 2013). *Information systems and software development* is a dynamic, interesting research area, which provides the finest and fastest way to solve typical problems.

Innovative evaluation of quality is introduced to design a database conceptual model which can result from a vertical mapping or a horizontal mapping (Locuratolo, 2014a). In the former case, the cost of specifications/proofs is given through the cardinality of variables and constants; in the latter case, the conceptual model is evaluated in terms of hidden classes. These represent the *saving* that is obtained for what has not been explicitly specified/proven. The hidden classes can also be exploited to test other quality desiderata/dimensions, such as *easiness of use* and *flexibility*. The numeric saving of consistency can be determined from the corresponding conceptual evaluations. The vice-versa is not possible.

In this article, a new approach to conceptual database design, called *evolving conceptual database design*, is introduced. The approach integrates a *structure for the preservation of classes/concepts* within the conceptual database design: starting from a database conceptual graph, an ontology defined at the boundary between concept theory and computer science, called *structure for the preservation of database classes/concepts*, is designed (Locuratolo, 2015b); the leaves of this structure are mapped to classes of a logical database model. A

constructive approach of logical database design is considered to handle some dynamic aspects of the conceptual database design and the quality of this approach is evaluated.

BACKGROUND

Model-driven engineering is an approach to software development that separates the specification of the system functionality from its implementation on a particular platform. A *model-driven architecture* makes models the primary artefacts of software engineering. The development consists in the definition of a platform-independent model (PIM) of a system and in the application of parameterized transformations to this PIM in order to obtain one or more specific platforms. Another important specification is *architecture-driven modernization*, which is the process of understanding and evolving existing software. It involves modifications, reuse and enterprise-application integrations. An approach to modernization is a way to revitalize existing applications and systems. It concerns a wide variety of models and mappings between models, allowing integration and transformation of those models. Over the last few years, *model-driven architecture* has been integrated with *enterprise information systems*, and other technologies, such as *semantic web*, *semantic web services*, and *ontology* techniques.

Graphs of classes representing *conceptual/ logical database models* are based on concepts which are common in *enterprise information systems*, *model-driven engineering*, and *ontology*. New engineering requirements and current technologies favour the *conceptual database design evolution*. In the following, definitions useful to the purposes of the chapter are introduced: first a description of the *conceptual database design* is provided; then an extension of some definitions is given.

Conceptual Database Design

D

In this section, definitions useful to introduce the concept of conceptual database design are given:

- **[Database Conceptual Class]:** Couple (v, V) , where v is a label denoting the class objects and connoting the corresponding concept, and V are the attributes associated with the objects.
- **[Is-a Relationship]:** Conceptual class (u, U) is in *is-a relationship* with conceptual class (v, V) iff
 - The objects of class (u, U) are enclosed into the objects of class (v, V) ;
 - The attributes of class (u, U) are inherited from class (v, V) ;
 - Class (u, U) can have specific attributes
- **[Database Conceptual Graph]:** Oriented acyclic graph G_c of database classes in *is-a* relationship.
- **[Revised Partitioning]:** Step-sequence of decompositions resulting in the *finest partition* of G_c . At each step of decomposition, the following properties hold:
 - **Root Partitioning:** The root objects of a conceptual graph G_c are partitioned into the root objects of the conceptual graphs obtained after the decomposition.
 - **Root Labeling:** The root labels of the graphs obtained from decomposition represent the partition. These labels are obtained combining the root label of the decomposed graph with the labels of the root directed descendants.
 - **Root Structuring:** The root labels can be decomposed into two parts separated by the “-“sign: that on the left of this sign consists of label intersections, whereas that on the right consists of label unions. One of the two parts can be empty.

- **Consistency:** The following implicit information is specified through the root labels: only the attributes of class $\langle u \rangle$ are associated with a node labeled by $\langle u - v \rangle$, whereas the attributes of all the classes $\langle v_1 \rangle \dots \langle v_n \rangle$ with the node labelled by $\langle v_1 \cap \dots \cap v_n \rangle$.
- **Object/Logical Graph:** The obtained disjoint classes can be recomposed into an object/logical graph G_0 .
- **[Database Logical/Object Graph]:** Oriented acyclic graph G_0 of database classes in $is-a_0$ relationship. The $is-a_0$ differs from the $is-a$ relationship since the objects of class $\langle u, U \rangle$ and the objects of class $\langle v, V \rangle$ are disjoint.

Properties

In a *database conceptual graph*, each object instance can belong to any class of the graph thus enhancing *flexibility*.

The *revised partitioning* gives the properties characterizing the partitioning algorithms, which are algorithms of mapping from conceptual to logical database models. The objects of class $\langle u, U \rangle$ are denoted by $\langle u \rangle$. Exploiting the [Revised partitioning] properties, attributes of both, the classes of the decomposed database conceptual graphs or the disjoint classes of a logical/object database graph, can be associated to the classes.

In a *database logical graph*, each object instance can belong to one and only one class of the graph, thus enhancing *efficiency*. In the following, extended notions are given for a *constructive approach of conceptual database design* (Locuratolo, 2013).

Constructive Conceptual Database Graphs

This section is based on the extensions of previous definitions:

- **[Extended Database Conceptual Class]:** Triple (v, V, Op) that enlarges the couple (v, V) of the *database conceptual class* with the set Op of *basic operations* to add/remove objects or modify the class attributes.

In (v, V, Op) , both *attributes* and *basic operations* are defined by *functions*. Specifically, the basic operations are predicate transformers preserving the conceptual class constraints, i.e., *functions from predicates to predicates*. The weakest precondition semantics for a basic operation op is the following:

$$[Op(v, V)(par_list)]R \Leftrightarrow (conceptual\ class-constraints(v, V) \Rightarrow conceptual\ class-constraints(v, V)^*) \wedge R^*$$

where R is a predicate on the variables of class $\langle v, V \rangle$, *conceptual class-constraint* is the predicate which formalizes the conceptual class definition, and the star predicates are the mentioned predicates after the operation. Taking into consideration this observation, also the extended conceptual class (v, V, Op) can be denoted by $\langle v \rangle$.

- **[Extended Is-a Relationship]:** The extended conceptual class $\langle u \rangle$ is in an *extended is-a relationship*, denoted by $is-a'$ with class $\langle v \rangle$, iff
 - The objects of the extended class $\langle u \rangle$ are enclosed into the objects of the extended class $\langle v \rangle$.
 - The attributes and the elementary operations of the extended class $\langle u \rangle$ are inherited from The extended class $\langle v \rangle$ the extended.
 - class $\langle u \rangle$ can have specific attributes and elementary operations.
- **[Extended Database Conceptual Graph]:** Oriented acyclic graph G'_C of *extended classes* in *extended is-a* relationships, denoted by $is-a'$.

Further steps of *extended database conceptual graph* based on set-theory extensions can be proposed.

Observation

In a database conceptual graph, classes can be in *multiple inheritance*, i.e., classes with more *is-a* links to other classes. However, as this situation can be approached through the graph decomposition in disjoint trees, in the following, the considered graphs will be limited to graphs without classes in multiple inheritance.

Innovative Evaluation of Quality

The techniques proposed for the evaluations of models can be *theoretical*, such as ontological evaluations, *empirical*, such as experiments and cases studies, or *mixed*, such as theoretical approaches with empirical experience (Krogstie, Halpin & Keng, 2005). These techniques, which are mainly based on *metric analysis*, *cognitive analysis* or *statistical approaches*, result in numerical values, qualitative or statistical evaluations of quality. A *conceptual “measure” of quality*, given in terms of *hidden classes*, is proposed in (Locuratolo, 2014a). In order to reach this achievement, two different kinds of mapping are considered: the former kind is a vertical mapping which starts from the specification of a database application supported by a formal model, and results in a model based on semantic data models (Cardenas & McLeod, 1990). The latter is a horizontal mapping which starts from a database conceptual graph and achieves the resulting model of the previous approach. The use of *database notations* and of *is-a relationships* allows the achievement of the following conflicting quality dimensions/desiderata: *easiness of use and flexibility*. *Consistency* is a further quality dimension/desiderata to be proved.

The vertical mapping is exploited as a means for:

- Justifying the achievement of the *quality dimensions/desiderata*.
- Giving a *quantitative/numerical evaluation* of the *consistency costs*.

The *quantitative evaluation* is a number that expresses the *consistency cost* of what has been specified/proven in terms of variable and constant cardinality. This number gives no indication about the opportunity to specify or to prove at a *good cost*.

The horizontal mapping design is exploited as a means for

- Justifying the achievement of the *quality dimensions/desiderata*;
- Giving a *qualitative/conceptual evaluation* of the *consistency costs*.

The *qualitative/conceptual evaluation* is a set of hidden classes/extended classes that express the *saving* for what has been *implicitly specified/proven*. This “*measure*” gives indication about the *model goodness*, since it is related to the hidden classes and to their semantic richness. Other dimensions of quality, such as *easiness of use* and *flexibility*, can be tested on the hidden classes. The saving of the consistency costs can be determined *numerically*, starting from the corresponding qualitative evaluation. The vice-versa is not possible.

MAIN FOCUS OF THE ARTICLE

The main focus of this article is concerned with the proposal of a new approach of conceptual database design, called *evolving conceptual database design*, which introduces the *structure for the preservation of database classes/concepts* within the conceptual database design. The quality of the proposed approach is evaluated. The *structure for the preservation of database classes/concepts* is designed starting from a database conceptual graph. The leaves of this structure are mapped to a *logical/object database graph*. Horizontal steps

of constructive logical database design extend the model. The computational costs required to design the *structure for the preservation of database classes/concepts*, as well as the qualitative/conceptual costs of the logical models resulting from the constructive design, are discussed. In the following, the solution is given to enclose the *structure for the preservation of database classes/concepts within the conceptual database design*.

Solution and Recommendation

Given a conceptual graph G_c , the following *is-a*^c relationship is introduced to design a *generalization hierarchy of classes/concepts* (Locuratolo, 2015a; Locuratolo, 2016a).

Concept $[v]$ *is-a*^c concept $[u]$ if class $\langle u \rangle$ *is-a* class $\langle v \rangle$ in G_c .

A *structure for the preservation of database classes/concepts* (Locuratolo, 2015) is an ontology, defined at the boundary between *concept theory* and *computer science* that encloses:

- All and only the *classes/concepts* related to the conceptual graph G_c ;
- All and only the *is-a*^c relationships among *classes/concepts*;
- All and only the incompatible concepts/disjoint classes, which are leaves of the structure.

The structure for the preservation of database classes/concepts has been designed to achieve the *class/concept completeness* property, i.e., the integration of h generalization hierarchies of classes/concepts resulting from *partitioning algorithms of maximum steps* applied to the conceptual graph G_c , with h is the number of the direct sons of G_c root (Locuratolo, 2014b). A *mapping* is then established between the leaves of the *structure for the preservation of database classes/concepts* and the classes of a *database logical/object graph* G_o . The *revised partitioning* properties are

exploited to associate attributes with the classes during the mapping approach from the leaves of the structure to the logical/object database graph G_o . A constructive approach to database logical/object database design is proposed to extend the logical model G_o .

In the following, the definition of extended database logical/object graph is given:

- **[Extended Database Logical/Object Graph]:** Graph of database logical/object classes G'_o in *extended is-a'* relationship, denoted by *is-a'*_o.

Class $\langle u \rangle$ *is-a'*_o class $\langle v \rangle$ iff the objects of class $\langle u \rangle$ are disjoint from the objects of class $\langle v \rangle$ and class $\langle u \rangle$ inherits both *attributes* and *basic operations* from class $\langle v \rangle$. Class $\langle u \rangle$ may have *specific attributes/basic operations*.

Steps of further *extended logical database design* based on set-theory extensions can be proposed to enrich further the database logical graph G'_o .

The approach is described in Figure 1: starting from the conceptual graph at the left side of the figure, the *structure for the preservation of database classes/concepts* is constructed and the leaves are mapped to a logical database graph. A new student employee is introduced in the appropriate class of the logical schema. In Figure 1, this operation is underlined.

Quality Evaluation

The quality evaluations of the *evolving conceptual database design* approach are based on the following costs:

1. Cost required to design the *structure for the preservation of database classes/concepts*;
2. Cost to map the leaves of the *structure for the preservation of database classes/concepts* to a database logical/object graph G_o ;
3. Cost of the *constructive logical database design*.

Figure 1. Approach description

In the following each of these costs is discussed:

Computational Cost

The cost required to design the *structure for the preservation of database classes/concepts* is the number of *classes/concepts* belonging to the structure. The algorithm resulting in the structure for the preservation of database classes/concepts is recursively defined starting from four initial cases. The formula introduced to evaluate the costs of the four initial cases is a function of the parameters n and h ; n is the number of the G_c classes, h is the number of the direct sons of the root. This cost, denoted by $C_1(h, n)$, gives the following values for the initial cases:

$$C_1(0, 1) = 1; C_1(1, 2) = 3; C_1(1, 3) = 5; C_1(2, 3) = 9$$

In the general case, this cost is *low* if G_c is a *single path tree*; it is *high* if G_c is a tree with only direct sons of the root, i.e. in the worst case,

and can be *acceptable* for applications with tree belonging to *intermediate cases*. An intermediate case can be transformed in the worst case, generating always necessary empty classes, which are not interesting in computer science but that can be interesting in concept theory.

The cost evaluation in the worst case is a function of the only parameter n . Specifically, it results $C_1(n) = 19/2 n!$ This cost represents an upper limitation to the complexity of the intermediate cases. As an example, $C_1(3) = 3 \cdot 19 = 57$ in the worst case, i.e. for a conceptual graph with three direct sons of the root and $C_1(2, 3) = 23$ for a conceptual graph with two direct sons of the root and three global sons. In the case in which the two direct descendents of the root have empty intersection, this cost is further reduced to 13.

Mapping Cost

The cost to map the structure for the preservation of database classes/concepts to the database logical graph G_0 is equal to the number of leaves of the

structure for the preservation of database classes/concepts. This cost, denoted by $C_2(n)$, is related to the conceptual tree topology, and its value belongs to the following interval: $n+1 \leq C_2(n) \leq 2^n$. The cost $C_2(n)$ is also the mapping cost of an algorithm of database graph partitioning initially introduced for the database conceptual design (Locuratolo & Rabitti, 1998). No approach of classes/concept preservation is part of this algorithm. In *evolving conceptual database design*, the *structure for the preservation of database classes/concepts* is part of the conceptual design. Although the mapping cost can be high in the worst case, its value can be really reduced for empty intersections among nodes, especially, in the case of applications with all the direct descendents of the tree root having empty intersections.

In (Locuratolo & Rabitti, 1998), both a table showing the mapping costs for tree with n nodes ranging in an interval from 1 to 16, where each node has at most p descendents ranging from 2 to 20 and a corresponding table showing the mapping cost for the same trees with disjoint direct descendents of the roots are provided. As a further observation, let us evidence that in real applications, not all the class/concepts of the *structure for the preservation of database classes/concepts* need to be mapped to the logical model, but only those where the corresponding logical class has at least one object. This observation can be useful exploited to handle the dynamic aspects of the *logical schema evolution* (Zicari, 1992).

Constructive Logical Database Design Cost

In order to evaluate the *costs of the constructive logical database design*, the following definition of specialized *logical class* is introduced:

- **[Specialized Logical Class]:** If (v, V) and (u, U) are logical classes, then class (u, U_e) , called *specialized logical class*, is defined as follows:

- class $\langle u \rangle$ and class $\langle v \rangle$ are disjoint.
- U_e is an enriched set of the attributes of class $\langle u \rangle$.
- Each attributes of class $\langle v \rangle$ is inherited by class $\langle u \rangle$.
- Each attribute of U_e belongs to class $\langle u \rangle$ or to class $\langle v \rangle$.

The *qualitative measure of quality* for a database logical graph G_o is defined subtracting from each specialized class (u, U_e) class (u, U) . Formally,

$$[u, (U_e - U)] = (u, U_e) - (u, U),$$

for each G_o class $\langle u \rangle$

This operation gives as a result, a class with the same label of the original class $\langle u \rangle$, and with attributes determined by set difference between the attributes of the specialized class, and those of the corresponding class. The “*measure*” of *quality* of the database logical graph represents *the saving* of implicit specifications. This saving can be determined *numerically* as a function of the specified variables and constants.

- **Property:** The “*measure*” of quality of an extended database logical graph G_o'' is the extension of the G_o' “*measure*” of quality.

This is a very interesting property: when the logical graph is extended, in order to evaluate the new saving, it is not required to begin *from scratch*. The new saving can be determined extending the previous saving. In order to be adherent with the other mentioned costs, in this paper, the *quality of the constructive, logical database design* is evaluated numerically. Finally, the following observation completes the section:

Observation

The *constructive logical database design* can be useful exploited to handle the dynamic aspects concerning the insertion/remotion of objects in the logical classes.

DISCUSSION

Semantic and object database models (Cardenas & McLeod, 1990) have similar mechanisms of abstraction; however, while semantic data models have never been implemented efficiently (Nixon & Mylopoulos, 1990), a remarkable level of efficiency has been achieved by object systems such as O2, or Object Store (Aloia, Barneva, Rabitti, 1992). On the contrary, while semantic data models are adequate for conceptual design, object database systems can display serious shortcomings in their ability to describe the dynamic nature of the real world entities.

The first algorithm of graph partitioning algorithm was proposed to achieve the two conflicting desiderata of *flexibility* and *efficiency*. Equivalence relations between conceptual and object database schemas ensure *correctness*. (Locuratolo & Rabitti, 1998). The results of this paper were used: within the refinement phase of the formal database design methodology ASSO (Locuratolo & Matthews, 1999; Locuratolo, 2005); to permit the database design to choose between two different kinds of target object models with different degrees of implementation efficiency, *Single Storage Object Data Model*, to retrieve an object with a single access; *Multi Storage Object Data Models*, to retrieve an objects with multiple storage access.

Algorithms of *graph partitioning*, exploited in conceptual database design, were reused to define a methodology of *database concept preservation* (Locuratolo & Palomäki, 2013; Locuratolo & Palomäki, 2015; Locuratolo, 2016b). Concept theory distinguishes *extensionality* from *intensionality*. In extensionality, a collection of objects is determined by its elements, whereas in intensionality, the interest is focused on concepts, properties, etc. It is possible to go from concepts to objects, not vice-versa. Although a formal background is available in concept theory, only recently, an algorithm, *the concept construction algorithm* was introduced (Locuratolo & Palomäki, 2013). The world of concepts is large and yet unexplored; on

the contrary, the world of database classes is well known. A relationship holds between an algorithm of graph partitioning, and the *concept construction algorithm*. The former results in disjoint classes that can be composed in a logical database graph; the latter in a concept structure, called *Ontology for database preservation*. It encloses:

- All and only the concepts related to an initial concept structure;
- All and only the logical relationships among the determined concepts;
- Results in leaves that can be mapped to a logical database graph.

Ontology for database preservation, which is formalized in concept theory, represents a concept structure difficult to be implemented, since it cannot enjoy the useful properties of the *is-a relationship*, exploited in modeling database conceptual graphs. The *structure for the preservation of database class/concepts* overcomes these problems since formalized in set-theory, and based on the *is-a^c* relationships.

FUTURE RESEARCH DIRECTIONS

The formal database design methodology ASSO has been defined to combine *easy* modification of the schema with *efficient* implementation, whilst ensuring specification *consistency* and design *correctness*. ASSO has been designed for *quality* achievements (Castelli & Locuratolo, 1995; Locuratolo & Matthews, 1999; Locuratolo, 2005). Object oriented methodologies, however, have always been very weak when dealing with data design; an example of methodology which overcomes this problem is IDEA (Ceri & Fraternali, 1997). In this methodology, data design comes first and application design follows. For the generalization hierarchies of IDEA, no transformation is required in the passage from analysis to design. The objects of a super class are partitioned into the objects of the subclasses.

This differs from the specialization hierarchy of the ASSO conceptual model, where the objects of the subclasses can overlap and a partitioning algorithm is exploited to map the conceptual model to the logical model. The methodology consists of two phases: conceptual design and refinements. The former focuses on the construction of the conceptual schema, a high level description of the database structure and behaviour. This schema is supported by a semantic data model extended with operations, modelled through predicate transformers. First order formulas permit to prove the conceptual schema consistency. Schema transformations resulting from appropriate extensions of the partitioning algorithms preserve the model semantics ensuring that the object schema is a correct implementation of the conceptual schema. The costs of the refinement approach of ASSO can be compared with the costs proposed in this chapter. From this evaluation, the opportunity to apply the *evolving conceptual database design* approach to the ASSO methodology results to be one of the possible future research direction.

CONCLUSION

This chapter proposes advancements of previously achieved research results: a new approach of conceptual database design, called *evolving conceptual database design* is proposed and the *quality* of this approach is evaluated. Specifically, the *structure for the preservation of database classes/concepts*, a concept structure defined at boundary between concept theory and computer science, is introduced within the *conceptual database design*: the *concept structure* is constructed starting from a database conceptual graph. The leaves of the concept structure are mapped to a *logical/object database graph*. Horizontal steps of constructive logical database design extend the model. The computational costs required to design the *structure for the preservation of database classes/concepts*, as well as the qualitative/conceptual costs of the logical models resulting from the constructive design, are discussed.

ACKNOWLEDGMENT

The author thanks Prof. Bruno Codenotti for the useful discussions during the preparation of this chapter; Dr. Paola Federica Canonico and Dr. Andrea Vannozzi for the technical support in the realization of the Figure.

KEY TERMS AND DEFINITIONS

Database Conceptual/Logical Class: Couple (v, V) , where the former component is a label denoting the class objects, and connoting the corresponding concept and the latter component is defined by attributes associated with the objects.

is-a Relationship: Conceptual class (u, U) is in *is-a relationship* with conceptual class (v, V) iff: the objects of class (u, U) are enclosed into the objects of class (v, V) ; the attributes of class (u, U) are inherited from class (v, V) ; class (u, U) can have specific attributes.

is-a^c Relationship: Concept $[v]$ is-a^c concept $[u]$ iff class (u, U) is-a class (v, V) in the conceptual graph G_c .

is-a_o Relationship: Relationship differing from the *is-a relationship*, since the objects of class (u, U) and the objects of class (v, V) are disjoint.

Qualitative/Quantitative “Measure” of Quality: Class defined “subtracting” from the specialized logical class (u, U_e) class (u, U) . Formally $(u, (U_e - U)) = (u, U_e) - (u, U)$. This class expresses the *saving* of implicit specification. From the qualitative “measure” of quality, the quantitative “measure” can be determined. The vice-versa is not possible.

Specialized Logical Class: Class (u, U_e) determined from class (u, U) is-a_o (v, V) : each attributes of class (v, V) is inherited by class (u, U_e) and each attribute of U_e belongs to class (u, U) or to class (v, V) .

Structure for the Preservation of Database Classes/Concepts: Ontology defined at the boundary between *concept theory* and *computer science* enclosing: all and only the *classes/concepts* related to a given conceptual graph G_c ; all and only the *is-a^c* relationships among *classes/concepts*; all and only the incompatible concepts/disjoint classes, which are leaves of the structure.

Query Languages for Graph Databases

D**Kornelije Rabuzin***University of Zagreb, Croatia*

INTRODUCTION

One can find more or less complicated definitions, but one could say that a database is an organized collection of data. It is assumed that a database is stored as files on a computer. Actually, any list of items on a paper could be called a collection of data as well, but today it is assumed that databases are stored digitally.

In order to create a text file, some text processor should be used (for example, Word, Wordpad, Notepad, etc.). In the same way, in order to create a database, some Database Management System (DBMS) should be used. Many systems are available, including Oracle, DB2, SQL Server, PostgreSQL, MySQL, Microsoft Access, Neo4j, MongoDB, etc. The majority of DBMSs are relational in nature. “Relational” means that the main structure that is used to store data is a relation, or as users usually call it, a table. One table contains zero or more rows. The idea of storing data into *relations* (tables) is quite old and relational databases have been used for over 40 years. Relations store data in a compact and organized way and redundancy and anomalies that are caused by redundancy are usually avoided. The relational model was introduced by dr. E. F. T. Codd. in the late 1960s and early 1970s.

In order to use a database management system, one has to be familiar with Structured Query Language (SQL). SQL is a standardized language that is supported by all major Relational DBMS software vendors (it does not belong to any vendor in particular). SQL contains many statements to work with data. The CREATE statement is used to create different objects in the database, as well as the database itself. The INSERT, UPDATE and

DELETE statements are used for data manipulation purposes. In order to retrieve data from one or more tables, SELECT statement is used. Many other, complex statements are available as well, but for our purposes, we can skip the details. Each DBMS has some (graphical) client program (one or more) that can be used to write queries (in SQL) in order to work with the database (for example, phpMyAdmin, Workbench, Navicat, pgAdmin, SQL Server Management Studio, etc.). More on SQL can be found in (Rabuzin, 2011, 2014).

Relational databases are mature technology; many DBMSs are available, SQL is standardized, etc. But in recent years things have changed. Extremely large amounts of unstructured and/or semi structured data come from different sources and relational databases can not cope with such large amounts of data in a satisfactory manner. Furthermore, certain queries require too much time to execute and sometimes such behavior is not acceptable. Because of this new types of databases are being invented (and used) on a daily basis, especially NoSQL technologies, which are becoming more and more important.

The word NoSQL had different meanings in the past (for example, No to SQL), but today people usually mean “Not Only SQL”. When one talks about NoSQL databases, several different types can be distinguished (some authors believe that XML databases should be included as well, as well as some other types, but it doesn’t make much difference):

- Document oriented databases,
- Column oriented databases,
- Key Value databases,
- Graph databases.

Document oriented databases, like MongoDB, do not use tables to store data. Instead, they use collections that store documents. Since one document contains all the data that are relevant, foreign keys are not used (at least not in a form that one is used to in relational databases). Document databases can use references to link between documents, but usually all the referenced data could/should be included within the document. So basically, collections would correspond to tables and documents would correspond to rows. It is important to have in mind that the document schema is flexible and each document within the collection can have different schema.

Column oriented databases use tables as well, but data is organized and stored differently. Unlike relational databases that store together values that belong to a single row (usually several rows are stored within a single unit of storage), column oriented databases store together values (for different rows) that belong to the same column. This is easy to justify. Namely, when one poses a query, in most cases one doesn't need all the columns in the table. Instead, only a few columns are usually selected. In data warehouses dimension tables can have very large number of columns. So queries that are posed on column oriented databases should be faster because less data has to be read from the hard disk drive since column data is stored together (and not values that belong to a single row).

Key Value (KV) databases store values for defined keys. Values can be simple as well as complex. Key value databases may look trivial, but sometimes they can be very useful.

For now it is important to have in mind that graph databases represent an interesting type as well, and because of that they will be discussed later. Namely, the main idea of this article is to present languages for graph databases so they have to be explored more thoroughly.

Although relational databases are the most commonly used, NoSQL databases have great potential. However, one has to have in mind that other database types (<http://db-engines.com/en/>) do exist (object oriented databases, content store,

event store, etc.), but they are not important for this research. So many different database types are available and they can be used for different purposes; one can store company data, images, sound, biometric data, etc. But the type that one plans to use depends on one's needs because all the database types mentioned above are more or less appropriate for different scenarios. For large amounts of interconnected data graph databases could represent the best choice whereas for large amounts of structured data relational databases may still represent the best choice. The idea behind NoSQL databases is not to suppress relational databases; it is just a question of the user's needs. So, relational databases now have an alternative, but which type to use depends on user's needs.

The main idea of this article is to explore several languages for graph databases. One of the languages that is in use is Cypher Query Language (CQL). However, it has some limitations as it will be shown later on. Because of that a new graphical language is proposed (implemented) that should be easier to learn and to use (at least for end-users). To resolve other limitations (recursion, views) that CQL has, it is shown how a logic programming language (Datalog) could be used as well.

So, the article is organized as follows. First, the background is described. Then CQL is explained. In the next two sections a new language for graph databases is proposed and implemented and then it is shown how a logic programming language could be used to write queries that are not supported in CQL. In the end future research is given and the conclusion is presented. Finally, references are listed.

BACKGROUND

Problems With SQL

When SQL was introduced, it was supposed to be simple. However, it turned out to be quite complex and end-users had problems with more complex queries. Although the idea was that SQL had to be simple so that end users could write the queries

Figure 1. Query by example in Microsoft Access

on their own, this was not the case. Namely, over the years several versions of the SQL standard became available (the version from the year 2008 had almost 5000 pages). Because of that even professionals can have problems with queries, and one query that could definitely cause problems to end-users is shown below (end-users are usually not capable of writing such queries):

```
SELECT TOP 100 calls.crm, calls.parent_id, calls.phone_c, izvor.broj_poziva
FROM calls INNER JOIN (SELECT crm, parent_id, phone_c, COUNT(*) broj_poziva FROM calls c GROUP BY crm, parent_id, phone_c) AS izvor ON
(calls.crm=izvor.crm AND calls.parent_id=izvor.parent_id AND calls.phone_c=izvor.phone_c) ORDER BY calls.crm, calls.parent_id, calls.phone_c, broj_poziva DESC
```

Since SQL queries can sometimes get complex, some other languages for relational databases were invented as well (in order to make the process of writing queries easier). One of them is called Query By Example (QBE) and it can be used in Microsoft Access (Figure 1). QBE is a graphical alternative to SQL. It should make it possible for end users to write queries successfully, although they do not have to know every SQL clause in order to write queries manually. This is one of the reasons why Microsoft Access is so popular.

In QBE one selects the attributes that one wants and one can enter certain criteria, specify the sort order and basically, this is enough to produce a query (Figure 1). This QBE idea is very important and it is going to be applied later on. Namely, the plan is to show that queries against graph databases could be built graphically as well. But first one should look at graph databases more thoroughly.

Figure 2. Graph database in Neo4j

Graph Databases

Graph theory is not new. However, such databases could be considered new. One small example of a graph database is given below (Figure 2).

Graph databases use vertices and edges to store information. The number of vertices and edges can be very large (measured in billions). The graph paradigm is a natural and very convenient way for some problem domains. For example, social network analysis is a good example. In order to represent a person and all the friends that the person has, and all the friends of friends (of the person), etc., a graph database is an excellent choice. For example, cities that are connected with roads, train stations, bus stations, etc., these are all scenarios that one could model by means of graph databases. Because of that graph databases are becoming more and more important, and at this point of time they are the database type that gains the most interest. However, for large amounts of structured (company) data relational databases would still represent the best choice. So each database type can be used for some problem domains, but it all depends on one's needs.

In (Robinson, Webber and Eifrem, 2013) one can find an interesting example. The example is about a database whose purpose was to store

information about people and their friends. It is important to say that relational database was used to store the database. Then SQL was used to build queries that should find friends of a person (the first level), then friends of friends were searched (the second level), etc. In the research authors also measured the time that was needed to get results to the queries. It is obvious that the “first level query” was executed almost immediately. The “second level query” took more time, and the “fifth level query” was even not executed in a real time. Since graph databases use edges to connect nodes, such queries are executed in a much faster way because in order to get a result to the query, it is enough to read the database (reading in graph databases is fast and there are no joins included as in SQL, because nodes are directly connected by means of edges).

There are many different graph databases available, including Neo4j, Titan, Giraph, FlockDB, AllegroGraph, ArangoDB, etc. All these systems use certain languages like CQL, Sparql, Gremlin, etc. All these systems have different characteristics (some are distributed, some support different query languages, some can work with extremely large volumes of data, etc.). In this article Neo4j has been used for implementation purposes. Neo4j is the most popular system for

graph databases (<http://neo4j.com/>). It has many users, many downloads, many organizations are implementing their databases in Neo4j, etc. Since Neo4j supports CQL, CQL has been selected to implement a new version of the language that is graphically oriented and that should behave as QBE does to SQL.

To conclude, in the past few years many NoSQL databases have emerged, including graph databases. NoSQL databases have certain advantages and they can be used in certain domains as an alternative to relational databases. In order to use graph databases, one needs to be familiar with specific languages like Cypher Query Language (CQL) or Gremlin. However, some statements in CQL can be considered too complex for end users (it is shown later on). Because of that the main idea of this article is to introduce and implement a new language for graph databases, called Visual Cypher, and to explore whether one of the existing, logic programming languages (Datalog), could be used on graph databases. The first language (Visual Cypher) is new and it has been implemented to pose queries on graph databases visually for the purpose of this article. Since CQL does not support recursion, views, etc., Datalog is used to show how to use recursion and views on a graph database. More information on NoSQL and graph databases could be found in (Buerli, 2012), (Redmond & Wilson, 2012) or (Robinson et al., 2013).

CQL

CQL is a query language for graph databases. CQL has many statements and some of them resemble those in SQL. The CREATE statement is used to create nodes and relationships (DELETE is used to delete them). MATCH is used to specify the graph pattern that should be matched and it is mostly used to get data from the database. WHERE is used to specify conditions and RETURN determines what should be returned. SET is used, for example, to set properties on nodes and relationships. One can

also use operators (comparison, mathematical, Boolean, etc). At the same time CQL uses some clauses that are used in SQL, like ORDER BY, etc.

The CREATE statement that is used to create the database that one can see in the Figure 2 is given below (this statements creates courses and relationships between them):

```
CREATE (p1:Course {name: "Mathematics",
ects: 7}),
(p2:Course {name: "Informatics"}),
(p3:Course {name: "Programming I",
ects: 7}),
(p4:Course {name: "Databases I"}),
(p5:Course {name: "Databases II",
ects: 6}),
(p6:Course {name: "Data warehouses
I", ects: 5}),
(p1)-[:PREREQ]->(p3),
(p1)-[:PREREQ]->(p4),
(p2)-[:PREREQ]->(p4),
(p4)-[:PREREQ]->(p5),
(p5)-[:PREREQ]->(p6)
```

The first part of the CREATE statement creates nodes. For example, p1:Course {name: "Mathematics", ects: 7} creates a node whose label is Course, and the rest of the statement is used to create relationships between nodes. For example, (p1)-[:PREREQ]->(p3) creates a relationship (called PREREQ) between two nodes that are identified by p1 and p3.

In order to list the database content, MATCH and RETURN clauses should be used. This is an equivalent to the SELECT statement in SQL. The following query searches for courses that are connected, i.e., PREREQ relationship exists between them:

```
MATCH (n:Course) -[:PREREQ]->
(m:Course)
RETURN n.name, m.name
n.name                m.name
Mathematics            Programming I
Mathematics            Databases I
```

Informatics Databases I
 Databases I Databases II
 Databases II Data warehouses
 I

One could also use WHERE, ORDER BY and LIMIT statements, but they are used in a pretty much the same way as in SQL. The problem with CQL is that it does not support recursion or views as it will be shown later on. This is why it is shown how to use two other languages to pose queries below. The first language is in fact a new visual language, Visual Cypher. The other is not new (Datalog), but it should enable deduction on graph databases (it will be used to implement recursion and views).

Some papers that are relevant for graph databases and graph query languages are (Cheng et al., 2008), (He & Singh, 2008), (Holzschuher & Peinl, 2013) and (Wood, 2009). However, none of the mentioned papers does include or mention a new language in the way it is proposed in the article. The ideas presented in this article have their roots in the project that explored deductive rules in data warehouses (Rabuzin, 2014a).

SOLUTIONS AND RECOMMENDATIONS

A New Language for Graph Databases: Visual Cypher (VC)

The first problem with CQL is that statements have to be created (entered) manually and sometimes this can cause problems for users. One can also say that another database language has to be learned (again). In order to pose queries on graph databases easily, a graphical interface has been developed. QBE was already mentioned earlier as a graphical alternative to SQL. In this section VC is presented and its purpose is to pose queries on graph databases graphically in the same way as QBE is used for relational databases. To the best of author's knowledge, this hasn't been done before.

Table 1. Neo4j database structure

Label Name	Property Name
Node Labels	
User	Firstname, Lastname
Book	Title, YearPublished
Author	Firstname, Lastname
Genre	Name
Relationship Types	
BORROWED	Connects_User_to_Book
WROTE	Connects_Author_to_Book
PART_OF	Connects_Book_to_Genre

In order to demonstrate how to use the language, here is graph database structure that is used in examples below (nodes and relationships, i.e., vertices and edges are specified):

The language is implemented by means of Neo4jClient library for.NET. The interface can be used to work with the developed database, but without the Neo4j console (this console is used to write CQL statements in Neo4j). For now one can create nodes (one or more) as well as relationships and one can also pose queries against the database.

The first example is used to add nodes and relationships (Figure 3). One can add a node, two nodes and a relationship, etc. Since such scenarios are simple, one can see in Figure 3 how to add three nodes and two relationships:

The query behind the Figure 3 is given below (this is the query that the tool creates based on the items that have been selected on the interface, and the query is then executed in Neo4j):

```
Neo4jDb.Instance.Client.Cy-
pher.Match("(u:User), (b:Book),
(g:Genre)")
.Where((Book b) => b.Title==book.
Title)
.AndWhere((Book b) =>
b.YearPublished==book.YearPublished)
.AndWhere((User u) =>
u.Firstname==user.Firstname)
.AndWhere((User u) =>
```

Figure 3. Adding three nodes and two relationships

```
u.Lastname==user.Lastname)
.AndWhere((Genre g) => g.Name==genre.
Name)
.CreateUnique("(u)-[:BORROWED
{DateBorrowed:'' + dateBorrowed +
''}]>(b)-[:PART_OF]>(g)")
.ExecuteWithoutResults();
```

If one would like to add users and relationships manually, by means of CQL, here is exactly what one should write in CQL (users should be added before, in separate queries):

```
MATCH (u:User), (b:Book), (g:Genre)
WHERE b.Title='Judita' AND
b.YearPublished='1521' AND
u.Firstname='Ivan' AND
u.Lastname='Horvat' AND g.Name='Epic
poem'
CREATE UNIQUE (u)-[:BORROWED
{DateBorrowed:'13.1.2015.'}]>(b)-
[:PART_OF]>(g)
```

It is obvious that the developed prototype (interface) represents a much easier way for adding three nodes and two relationships than the CQL

query (the statement is generated automatically while the CQL query has to be entered manually).

Figure 4 shows how the interface for querying data (for a single node) looks like:

Figure 5 shows how to extract data from several nodes:

The method that has to be executed to extract the data is given below (it is used to retrieve data from the database):

```
IEnumerable<Object> result = Neo4jDb.
Instance.Client.Cypher
.Match("(user:User)-[:BORROWED]-
>(book:Book)<-[:WROTE]-
(author:Author)")
.Where((User user) => user.
Firstname==criteria1Prop1Node1)
.OrWhere((User user) => user.
Firstname==criteria2Prop1Node1)
.Return((user, book, r, author)
=> new { User=user.As<User>(),
Book=book.As<Book>(), R=r.
As<BORROWED>(), Author=author.
As<Author>() })
.OrderBy("user.Firstname")
.Limit(Convert.ToInt32(limit))
.Results.ToList<Object>();
```

Figure 4. Extracting data: single node

Figure 5. Extracting data: multiple nodes

To conclude, the developed interface can be used to add nodes and relationships as well as to extract data from the database. Other, more simple and complex examples could have been added as well, but the principle would have been the same. The main advantage of the approach is that users do not have to write CQL queries manually.

Instead, the visual interface makes the process of posing queries much easier. However, some other things should be implemented as well, like how to create other types of objects (for now one can create vertices and edges and one can retrieve data from the database), etc.

Datalog for Graph Databases

In this section Datalog is discussed in order to determine whether Datalog could be used to express queries on graph databases. Datalog is an old logic programming language and it is not explained here because people that work with databases are familiar with facts, rules and goals. However, the question is why to use Datalog on graph databases at all.

First of all, CQL does not support recursive queries. When SQL was introduced, it did not support recursive queries either. But some ideas from logic programming turned out to be very useful (recursive queries, for example). So today one can write recursive queries in SQL. CQL is probably on the same path and it is reasonable to expect that it will support recursive queries (some day), but for now it does not.

Second of all, views are not supported in CQL. In Datalog this is easy to achieve. If one had a rule, one could just call it and execute it as a query. In such a way the problem of views (that are not supported in CQL) could be resolved as well.

Furthermore, there are some other things that logic programming languages do support (hypothetical queries, for example), but for now the idea is to show how Datalog could be used to resolve two CQL problems that are mentioned above. In order to resolve the problems Datalog Educational Systems (DES) is used for testing purposes (in this section).

The graph database that was introduced to explain graph databases is used as an example. In order to find courses and their prerequisites in CQL, it is enough to read the graph database. It was noted earlier that MATCH and RETURN clauses (in CQL) should be used to extract data from the database:

```
MATCH (n:Course)-[:PREREQ]-
>(m:Course)
RETURN n.name, m.name
```

To find courses and their prerequisites on the second level, things get a little bit more complex, i.e., one has to add three nodes and two relationships to get the result:

```
MATCH (n:Course)-[:PREREQ]-
>(m:Course)-[:PREREQ]->(o:Course)
RETURN n.name, o.name
```

In order to find courses and their prerequisites (the first two levels), UNION should be used (UNION combines two queries in order to merge their results):

```
MATCH (n:Course)-[:PREREQ]-
>(m:Course)
RETURN n.name AS c, m.name AS p
UNION
MATCH (n:Course)-[:PREREQ]-
>(m:Course)-[:PREREQ]->(o:Course)
RETURN n.name, o.name
```

The same analogy could be applied further on (third level, etc.). But if one was not familiar with the total number of levels, such approach would not represent a good choice as queries would become more and more complex with each level. Imagine the query that finds courses and their prerequisites if one assumed that the total number of levels would be five.

In order to be able to use Datalog, the graph database should be transformed into a set of facts. But one thing is interesting here. Some graph database systems store graph databases in a native (graph) form, whilst some use relational or other types of databases for storage purposes. So, the thing that is crucial here is that relational representation of a graph database exists, in certain cases. This is the answer to the question and the reason why one could use Datalog on graph databases as well. But for the purpose of this example, one could transform nodes and relationships (from the graph database above) into a simple set of facts (only some courses are transformed to make this example small):

```
course('databases I', null).
course('databases II', 6).
course(mathematics, 7).
course(informatics, null).
```

The last course does not have the number of points, so NULL is used. NULL is used when one has to store data, but information is not known or it may be not applicable. The relationships between nodes could be transformed as follows:

```
prereq(informatics, 'databases I').
prereq(mathematics, 'databases I').
prereq('databases I', 'databases II').
prereq('databases II', 'data warehouses I').
```

After the facts are specified, the following rule could be defined:

```
comes_before(X,Y):- prereq(X,Y).
comes_before(X,Y):- prereq(X,Z),
comes_before(Z,Y).
```

This rule should find all the courses and their prerequisites (it is not required to know the number of levels in advance). This should be much easier than the example above (UNION in CQL).

And finally, a view is defined. When called, it lists all the courses that have 7 points. Such courses require special attention (the more points the course has, the more difficult it is):

```
attention(X):-course(X,Y), Y=7.
```

So now one could try to write queries and see their results. For a start, comes_before (X,Y) rule was invoked (Figure 6):

One can see that it is much easier to find courses and their prerequisites in Datalog, then it was in CQL.

The next query finds the courses that come before the course 'Databases I':

```
DES> prereq(X,'databases I')
{
  prereq(informatics,'databases I'),
  prereq(mathematics,'databases I')
}
Info: 2 tuples computed.
```

In CQL one should write the following query:

```
MATCH (x:Course)-[:PREREQ]->(Course
{name:'Databases I'})
RETURN x.name
In order to find courses that require special attention, one should use:
```

Figure 6. Datalog in action

```
DES> attention(X)
{
  attention(mathematics)
}
Info: 1 tuple computed.
```

In CQL one should write:

```
MATCH (x:Course) WHERE x.ects = 7 RE-
TURN x.name
```

One can see that Datalog queries are less complicated than their equivalents in CQL. This has certain advantages. One of them is that Datalog has been used for a longer period of time and people are familiar with facts and rules. Furthermore, some things that cannot be expressed in CQL can be expressed in Datalog. In this section Datalog was not explained in a high detail, but for more information one could look at (Colomb, 2005) or (Piattini & Diaz, 2000).

FUTURE RESEARCH DIRECTIONS

Three languages for graph databases have been analyzed. CQL is a language that is used in Neo4j and both the language and the system are quite popular. However, people that work with databases do have to learn another new language to use graph databases. Since the number of graph databases as well as the number of languages is very large, the main idea of this research was to invent another, graphically oriented language that resembles to SQL alternatives (like QBE). This new language was introduced (Visual Cypher) and the interface to use it was implemented. As a consequence, queries on graph databases can be posed graphically, in a similar manner as QBE can be used to pose queries on relational databases (graphically).

Currently the prototype is functioning very well, although additional functionality certainly should be implemented. For example, currently one can define/create nodes and relationships, and one can query the nodes and relationships, but one cannot create other objects in the database.

Finally, since CQL and VC do not support recursion and views, it was shown how Datalog could be used to perform recursive queries as well as how it can be used to define views. Datalog is a well-known language that has been used for a very long period of time and people are usually familiar with rules, facts and goals (queries).

In the future one could extend the VC (as described above) and one could certainly explore other graph databases and their languages in the context of this research. For example, Visual Gremlin could be implemented, etc.

CONCLUSION

In this article three languages for graph databases have been discussed. The first language is called Cypher Query Language (CQL) and it can be used in some systems, such as Neo4j. However, it has some limitations; queries have to be specified manually, views are not supported, recursion is not supported, etc. Because of this the second language is proposed and implemented, called Visual Cypher. It is a new, graphically oriented language that makes it possible to add nodes and relationships into the graph database, as well as to extract data from the database. However, some more advanced features should be added as well. The third language (Datalog) is not new and it has been used for many years. However, since Datalog supports recursion and views, it has been shown how to use recursion and views on a relational representation of the graph database.

KEY TERMS AND DEFINITIONS

Cypher Query Language (CQL): In order to use graph databases CQL could be used, but other languages do exist as well.

Datalog: A logic programming language that is important for deductive databases.

Graph Databases: A database type that uses vertices and edges to store information.

NoSQL: New database types that are used as an alternative to the relational data model.

Query By Example (QBE): Visual query language supported in Microsoft Access.

Structured Query Language (SQL): A standardized language for relational databases.

Visual Cypher: A new, proposed graphical language for graph databases.

Schema Evolution in Conventional and Emerging Databases

University of Sfax, Tunisia

INTRODUCTION

In information systems, not only do data change over time, but also database schemata evolve frequently (Sjøberg, 1993). Changing database schema, which is a common but often troublesome task in database administration, occurs for many reasons such as changes in user requirements, compliance to new regulations, addition of new functionalities, or correction of deficiencies in the current schema. Usually, the database administrator changes a database schema through a schema definition language (e.g., SQL DDL).

Two fundamental aspects are involved by schema change: (i) *semantics of change*, which deals with the effects of the change on the schema itself, in order to maintain schema consistency after schema changes, and (ii) *change propagation*, which deals with the effects of the change on the underlying data, in order to guarantee data consistency with the modified schema.

For most database applications, changing the schema of the database without loss of existing data is a significant challenge: it is usually a time-consuming and error-prone task which must be done carefully. In the literature (Jensen et al., 1998), *schema evolution* has been defined as the modality for the management of schema

changes which relieves database programmers and administrators from this burden, by automatically recovering extant data and possibly adapting them to the new schema. During the last two decades, a lot of theoretical work has been done on schema evolution in conventional databases, within the relational, object-oriented, and XML settings, as described in (Brahmia et al., 2015). In recent years, the schema evolution problem has been addressed also in emerging databases (e.g., temporal, genome, embedded, mobile, and NoSQL databases), as a consequence of the growing use of these new databases by contemporary applications (e.g., digital libraries, mobile applications). However, schema evolution support remains so far almost neglected at the practical level: existing commercial systems (i.e., DBMSs like Oracle and DB2, and schema management tools) only provide a quite limited support. Thus, currently, each database administrator uses ad hoc techniques to manage the evolution of a database schema.

The main goal of this chapter is (i) to present the recent research proposals, not already covered in (Brahmia et al., 2015), that deal with schema evolution in traditional and emerging databases, and (ii) to discuss the recent advances on schema evolution support in mainstream DBMSs. The rest of this chapter is organized as follows. The next

section gives some background on our subject. In “Recent Research on Schema Evolution”, we present an update on recent research proposals concerning schema evolution. “DBMS Support for Schema Evolution” surveys the support of schema evolution in the state of the art of the latest database technology. Finally, future work directions and conclusion are provided.

BACKGROUND

In this section, we illustrate with a simple example the functioning of schema evolution, contrasting it with the lowest level of schema change support that can be embedded in a database, that is the modality of schema modification (Jensen et al., 1998). Assume that we have a relational database that contains only an AUTHOR relation with the attributes ID (primary key), NAME, PHONE, and COUNTRY. The first state of this database is shown in Figure 1.

The catalogues store information on the schema S1 of the AUTHOR relation. The table AUTHOR contains two tuples for two authors. Then consider the following schema changes:

```
ALTER TABLE AUTHOR
DROP COLUMN PHONE;
```

Figure 1.

S1

AUTHOR(ID, NAME, PHONE, COUNTRY)

ID	NAME	PHONE	COUNTRY
1	Aicha	11223344	Tunisia
2	Cristiana	55667788	Italy

Figure 2.

S2

AUTHOR(ID, NAME, COUNTRY, EMAIL)

ID	NAME	COUNTRY	EMAIL
(empty)			

```
ALTER TABLE AUTHOR
ADD COLUMN EMAIL CHAR(30);
```

The schema modification technique allows users to effect changes to the database schema, but neither previous schema nor its underlying data are preserved: the old schema is replaced by the new schema, which is initially empty as data populating the old schema are discarded. The effects in our example would be as shown in Figure 2.

The database designer or administrator must restore information concerning authors Aicha and Cristiana in database state S2 by explicitly inserting them as new tuples, through the following SQL statements (executed within the same transaction containing the schema changes or later):

```
INSERT INTO AUTHOR
VALUES(1, 'Aicha', 'Tunisia', 'aicha@
author.tn');
INSERT INTO AUTHOR
VALUES(2, 'Cristiana', 'Italy',
'cristiana@author.it');
```

Hence, this solution leads to loss of information and obsolescence of applications developed according to the original schema. Although this technique may seem unsuitable, since it is straightforward to implement, it is actually the most widely

Figure 3.

S2			
AUTHOR(<u>ID</u>, NAME, COUNTRY, EMAIL)			

ID	NAME	COUNTRY	EMAIL
1	Aicha	Tunisia	Null
2	Cristiana	Italy	Null

adopted technique for managing schema changes in existing information systems.

With schema evolution, after a schema change the old schema is replaced by the new one and old extant data, which are still conforming to the new schema, are automatically recovered. In our example, the effects would be as shown in Figure 3.

The new email information could then be introduced through the following SQL statements replacing Nulls with correct values:

```
UPDATE AUTHOR
SET EMAIL='aicha@author.tn'
WHERE ID = 1;
UPDATE AUTHOR
SET EMAIL='cristiana@author.it'
WHERE ID = 2;
```

The final state of the database is as shown in Figure 4.

Schema evolution can anyway lead to a partial loss of information. For instance, dropping columns means losing the related data. The change of the type of a column could lead to loss of data of this column if the new type is not compatible with the previous type. Furthermore, schema evolution technique does not guarantee continued functioning of existing applications, since programs that

use dropped columns or columns having changed types become obsolete after a schema change.

RECENT RESEARCH ON SCHEMA EVOLUTION

In recent years, the problems raised by schema evolution in conventional databases (i.e., relational and XML databases) have been further studied, with respect to what we surveyed in (Brahmia et al., 2015). Lately, researchers of the database community have also investigated schema evolution in emerging databases (e.g., mobile, genome, and NoSQL databases). In the two following subsections, we present the main recent contributions concerning schema evolution in conventional and emerging databases, respectively.

Schema Evolution in Conventional Databases

In this subsection, we further classify the research proposals dealing with database schema evolution into two subsections, according to the type of the setting, that is (object-) relational or XML, in which the research work has been done.

Figure 4.

2	Cristiana	Italy	cristiana@author.it

Schema Evolution in (Object-) Relational Databases

In (Desanti et al., 2013), the authors propose an approach for schema evolution, based on a redundancy-free algorithm which removes possible redundancies in a set of schema change operations (i.e., a set of SQL DDL statements) specified on a relational database schema. A schema change operation is a “create”, “drop” or “modify” operation. The proposed approach (i) generates a delta version (i.e., a set of SQL DDL commands) with the difference between two schemas provided by a development team member, and (ii) merges a set of delta versions in one redundancy-free delta, by identifying and removing their redundancies, and executes such a delta, when the database administrator decides to generate a new version of the database schema.

Cleve et al. (2015) propose a systematic approach to understand how developers deal with database schema evolution in practice. It is based on an automatic four-step process in order to derive the global historical schema of an evolving relational database: (i) SQL code extraction, (ii) schema extraction, (iii) schema comparison, and (iv) visualization and exploitation. The produced schema contains all schema components that belonged (in past versions) or belong (in the current version) to the schema of the studied database, annotated with historical metadata (e.g., commit date, committer id).

Recently, Herrmann et al. (2015) propose CoDEL, a relationally complete database evolution language, which is built on the PRISM++ language (Curino et al., 2008a; Curino et al., 2010). CoDEL is intended to be a declarative language that consistently allows the specification of changes to the database schema and/or changes to stored data. Unlike PRISM++, CoDEL supports all possible schema change operations on tables. Relationally complete means that for any (relational) SQL script, which includes a sequence of SQL data definition and data manipulation statements, a semantically equivalent sequence

of CoDEL operations (i.e., SMO (Curino et al., 2008a) operations) exists. For each CoDEL operation, the authors formalize its operational semantics and provide an SQL-like syntax.

Schema Evolution in XML Databases

In (Klímek et al., 2012), the authors propose eXolutio, a tool which uses the principles of “Model Driven Architecture” (MDA) (Miller and Mukerji 2003) to design and evolve an XML Schema. It allows a designer to specify a “Platform Independent Model” (PIM) schema and multiple “Platform Specific Model” (PSM) schemata, each representing a part of a PIM schema, with a mapping from PSM schemata to the PIM one. eXolutio allows also the designer to evolve the set of specified schemata consistently, thanks to mappings between the two levels and propagation of schema changes made in one level to all the affected schemata.

As for updating XML documents, recently Cavalieri et al. (2013) proposed an algorithm for synthesising the changes between two XML documents as “Pending Update Lists” (PULs), that is unordered lists of update operations. If changes are represented as XQuery Update Facility (W3C, 2011) expressions, the evaluation of each expression results in a single PUL. Two phases are identified in the evaluation of an XQuery Update Facility expression: (i) production, in which the expression is evaluated producing a PUL, and (ii) application, in which the update operations in the produced PUL are applied.

In (Nösinger et al., 2013), the CoDEX approach of Klettke (2007) has been extended with “Evolution Language for XML-Schema” (ELaX), a domain-specific language that proposes to handle modifications on an XML Schema and to express such modifications formally. ELaX allows (i) specifying complex modifications by combining the add, delete, and update operations, and (ii) logging modifications on schema, which is an essential step for the adaptations of XML documents associated to XML Schema. Since an

XML Schema designer using the ELaX language could store a sequence of ELaX operations in a log for a long time period and execute it when required, Nösinger et al. (2014) propose a rule-based optimization algorithm “Rule-based Optimizer for ELaX” (ROfEL), which allows reducing the number of the logged operations before submitting them to be executed by (i) merging some of them, (ii) deleting unnecessary or redundant operations, and/or (iii) correcting, if possible, or removing invalid operations. Notice that the ROfEL algorithm applies a set of heuristic rules in order to identify unnecessary and redundant operations.

Amavi et al. (2014) propose a set of tools for conservative XML schema evolution and compatible XML document adaptation. They propose (i) an algorithm, which generates mappings that allow transforming an original schema into a conservative extension of it (and vice versa), via composition and inversion, and (ii) a method for translating each XML document which is valid to an original schema into a document which is valid to the extended schema.

Schema Evolution in Emerging Databases

Since contemporary applications, like multimedia, geographical information systems, digital libraries, and mobile applications, require new database models with new query languages for managing new types of data, new types of databases have emerged in the last few years. Among these emerging database paradigms, we could cite as examples multimedia, spatial, temporal, stream, biological/genome, embedded, mobile, grid, Big Data, and NoSQL/NewSQL databases. In the following paragraphs, we present contributions dealing with schema evolution in stream, embedded, and NoSQL databases.

Terwilliger et al. (2010) deal with schema evolution support in data stream management systems. They (i) propose to introduce a new element into data streams, called an accent, which announces evolutions to operators in a standing query, and

(ii) define a set of six common stream query operators (Select, Project, Union, Join, Window, and Aggregate) that can process data and schema evolution accents, considering three evolution primitives: “Add Attribute, Drop Attribute, and Alter Data”. So, the proposed framework allows data stream systems to support schema evolution without interrupting the evaluation of standing queries (i.e., queries respond automatically to evolution), whenever the evolution do not affect the semantics of a query.

Wu and Neamtiu (2011) propose an approach for automatically (i) extracting embedded database schemata from regular applications (e.g., written in C or C++), and (ii) detecting changes of these schemata as applications evolve. In fact, they present a tool, called “Schema extraCtion and eVolution analysis for embedded Databases” (SCVD), which shows the feasibility of their approach in the following way: given a set of releases of an application, SCVD automatically retrieves the source code for all these releases, extracts the database schemata embedded in each version of the application code, compares the extracted schema versions, and produces the schema evolution results organized in a useful manner.

In (Scherzinger et al., 2013), the authors aim at providing a generic interface for managing schema evolution in NoSQL data stores (Cattell, 2010). To that end, they propose (i) a declarative NoSQL schema evolution language (i.e., a set of basic common practical schema change operations that deal with most of the typical cases which are discussed in developer forums), and (ii) a generic and abstract NoSQL database programming language for accessing NoSQL data stores. The second language distinguishes the current state of the data store from the state of the objects available in the application space, and implements the proposed set of schema evolution operations. Through such an implementation, the authors show that the schema evolution process could be handled not only eagerly (i.e., executing the specified schema evolution operations directly on all involved entities), but also lazily (i.e., executing

the specified schema evolution operations on the concerned entities the next time they are fetched into the application space).

In (Scherzinger et al., 2015a), the authors propose Cleager, a web-based system prototype that allows eager schema evolution in schema-less NoSQL document stores (e.g., MongoDB, Google Cloud Datastore) by supporting the declarative NoSQL schema evolution language presented in (Scherzinger et al., 2013). Cleager (i) provides a web-based console for specifying eager schema modification operations, using the Cleager language (Scherzinger et al., 2013), and (ii) translates the specified operations and executes them as MapReduce jobs in the Google Cloud Platform.

In (Scherzinger et al., 2015b), the authors present ControVol, an Eclipse plugin which helps developers in resolving problems related to schema evolution during the process of development of Big Data applications on top of schema-less NoSQL data stores. Indeed, at development time, ControVol (i) detects changes (e.g., addition, renaming, or deletion of attributes) to the schema, in the application code, which are not compatible with legacy data; (ii) reports warnings to developers; (iii) proposes automatic and quick fixes to resolve the warnings. Consequently, ControVol guarantees, in the production environment, that not only legacy data could be compatible with new structures utilized in the new application code version, but also the new application version could continue running on legacy data.

Recently, Saur et al. (2015) propose “Key-Value store evolution” (KVolve), an approach and a tool for evolving a key-value NoSQL database without downtime. KVolve is implemented on top of a Redis (Redis Labs, 2015) NoSQL database which stores JSON (JSON, 2015) objects. It provides a domain-specific language to developers, which allows them writing changes to data formats (i.e., JSON objects) and specifying how legacy data are transformed to a new data format version. Such changes are applied lazily to the NoSQL database, in order to avoid downtime and database locking; objects that are stored according to a pre-

vious format are migrated on-the-fly to the new format only when accessed by applications. The developed tool supports changes to the fields of a JSON object (addition of new fields, and deletion or modification of existing fields) and also to the names of the keys.

DBMS SUPPORT FOR SCHEMA EVOLUTION

As reported in detail in (Brahmia et al., 2015), several survey works considered and comparatively analysed schema evolution support in traditional databases (Türker, 2000; Colazzo et al., 2010; Hartung et al., 2011; Curino et al., 2013). Such studies involved recent releases of all major commercial (object-)relational and XML DBMSs (including Oracle, Microsoft SQL Server, IBM DB2, MySQL, PostgreSQL, Sybase, Ingres, and Tamino), and change management tools (including Altova, IDERA, Embarcadero, RedGate, DTM DB, SwisSQL, and Liquibase).

Overall, these works show that the existing conventional DBMSs (i) support schema evolution partially, by providing only a limited set of schema changes, and (ii) do not use a common language to evolve schema. Besides, they show also that the support of XML schema updates (i) is either absent in some commercial DBMSs (like Microsoft SQL Server) and XML tools (like OXygen’s XML Editor or Stylus Studio) or (ii) limited in some other commercial DBMSs (like Oracle 11g, Tamino, or DB2 v.9) and XML tools (like Altova’s XMLSpy and DiffDog).

As for emerging DBMSs, Scherzinger et al. (2013) study, among other things, schema evolution support in state-of-the-art NoSQL data stores (Redis (Redis Labs, 2015) and Riak (Basho Technologies, 2015) as key-value stores, MongoDB (MongoDB, 2015) and Couchbase (Brown, 2013) as document stores, and BigTable (Chang et al., 2008), HBase (Apache, 2015a), App Engine Datastore (Google, 2015) and Cassandra (Apache, 2015b) as extensible record stores) and

present the results that follows. First, most NoSQL database systems do not provide a schema definition language (exception for some systems like Cassandra which supports a “CREATE TABLE” statement). Second, all existing NoSQL systems do not provide support for migrating legacy entities to a new schema specification and delegate such a task to the application logic layer. Third, in all available NoSQL data store systems, there is a lack of a schema evolution interface that helps in the maintenance of entities’ structures; currently, all schema changes are programmed by developers. Fourth, only Cassandra supports altering schema explicitly through its “ALTER TABLE” statement. So, it is not considered as a schema-less or schema-flexible NoSQL system. Fifth, NULL values, which result from some schema evolution operations (like adding a new field or column), are managed differently by NoSQL systems.

Moreover, in (Störl et al., 2015), the authors survey the state-of-the-art of Object-NoSQL Mappers, which are currently used by application developers to deal with schema evolution problems in schema-less NoSQL data stores, since available NoSQL systems do not provide any support for evolving schema of these data stores. Notice here that the lack of such a support could be due to the nature of these databases themselves which are designed to be schema-less or schema flexible.

FUTURE RESEARCH DIRECTIONS

There are several open research issues for schema evolution. Some of them are as follows:

1. Schema evolution is poorly supported in commercial DBMSs and schema management tools, as shown in the previous section. Thus, this aspect needs further efforts in order to provide more efficient practical solutions for database designers and administrators. Moreover, schema evolution support is also limited in the standard SQL language. Since relational databases continue to be the most

used ones around the world and since schema changes are unavoidable in information systems, SQL should be extended in order to provide more consistent help in managing evolving database schemata (e.g., new schema change operators, new features for graceful application of change propagation, etc.).

2. Nowadays, many enterprises use Web and distributed databases and, thus, schema changes have to be effected more frequently, since user requirements, laws and technologies rapidly change in this context. Therefore, it will be very interesting and useful to study schema evolution in Web and distributed environments. Among the first works in this area, we find (Curino et al., 2008b), which proposes a workbench for schema evolution in Web information system (after studying the Wikipedia database evolution during 4.5 years), and (Rae et al., 2013), which describes techniques used by Google’s F1 database management system (Shute et al., 2013) to support schema evolution in a globally distributed environment.
3. The database provenance is very useful in many modern information systems (like big science projects), in order to explain the lineage of the current data. This explanation often requires “flashing back” to the original schema. Thus, supporting database provenance under schema evolution could be an interesting issue. A first work in this area is (Gao & Zaniolo, 2012), which presents the main features of the Archived Metadata and Provenance Manager (AM&PM), which is the first system designed to support the provenance of both data and meta-data in the presence of schema evolution.

CONCLUSION

In this chapter, we studied recent advances on schema evolution in traditional and emerging

databases, and explored its support in commercial database systems and development tools.

Although a lot of work has been done at theoretical level and efficient solutions have been proposed by researchers, there is no efficient practical support for schema evolution at the state-of-the-art of database technology. Manual efforts are still required to successfully manage the schema evolution process: the database designer or administrator has to manually convert data defined under the previous schema in order to be valid with respect to the new schema, and the application developer(s) must carefully revise existing applications to adapt to the new schema.

KEY TERMS AND DEFINITIONS

Database Conversion/Migration: Process consisting in adapting data valid under a given schema version to another schema version.

Database Schema: The formal structure of the database, described by means of a data definition language.

Schema Change Propagation: The effects of a schema change at instance level, involving suitable conversions necessary to adapt extant data to the new schema.

Schema Change Semantics: The effects of a schema change at schema level.

Schema Changes: Operations performed on a (populated) database schema, in order to adapt it to new application requirements.

Schema Evolution: A schema change modality that avoids the loss of extant data. No support is required for previous schemata.

Temporal Database: A database with built-in support for managing time-varying data.

INTRODUCTION

Persistent information and data-centric systems use databases to store data. The contents of a database must adhere to a formal structure that is fixed in advance, and is called the schema of the database (Date, 2003). In those systems, not only data changes are obvious tasks done almost every day but also schema changes are unavoidable, in order to reflect a change in the real world or in the user's requirements, to correct mistakes in the initial design, to migrate to a new platform or to allow the expansion of the application scope over time. Two main problems have to be considered when dealing with any schema change: *semantics of change* (i.e., the effects of the change on the schema itself) and *change propagation* (i.e., the effects of the change on the underlying data). Resolving the former guarantees schema consistency, while resolving the latter guarantees consistency of data with respect to the changed schema.

In the literature, *schema evolution* and *schema versioning* (Roddick, 1995; Jensen et al., 1998) are the two techniques that were proposed to support schema changes in a DBMS, without loss of extant data and with continued support of legacy applications. After applying schema changes,

schema evolution keeps only the current schema version and retains the data which are adapted to such a schema. On the other hand, each time schema changes are applied, schema versioning creates a new schema version, while preserving old schema versions and their corresponding data. With schema versioning, data access through any schema version is supported, which avoids applications developed with past schemata to become obsolete.

Schema versioning has been widely investigated, both in the context of traditional and temporal database research. Several models, languages and approaches, dealing with schema versioning, have been proposed during the two last decades in the relational, object-oriented, and XML databases. However, to the best of our knowledge, limited support of schema changes and no support of schema versioning is provided by commercial database management systems (DBMS). Therefore, diligent database designers and administrators have to work hard to solve the problem of evolving a database schema in an ad hoc manner. Besides, with the growing use of emerging databases (e.g., multimedia, temporal, biological, and NoSQL databases), research work has also recently done on the problems of schema versioning in such settings.

The main goal of this chapter is (i) to present the recent research proposals, not already covered in (Brahmia et al., 2015), that deal with schema versioning, and (ii) to discuss the recent advances on schema versioning support in mainstream DBMSs. In particular, the next section gives some basic definitions related to the considered subject. In “Recent Research in Schema Versioning”, we present an update on recent research proposals on schema versioning. “DBMS Support for Schema Versioning” surveys the support of schema versioning in the state of the art of the latest database technology. Finally, future work directions and conclusion are provided.

BACKGROUND

The schema versioning technique allows changes to the database schema with continued support of previous schemata and their corresponding data, which are retained without any change. The newly created schema version is (usually) used to accommodate new data insertions, modifications and deletions. This technique neither leads to loss of information nor to obsolescence of existing applications, as they can still work with old schema versions. Further issues related to schema versioning support have been discussed in (Brahmia et al., 2015).

In this section, we illustrate the functioning of schema versioning with a simple example. Let us assume that we have a relational database that contains only an AUTHOR relation with the attributes ID (primary key), NAME, PHONE, and COUNTRY. The first state of this database is shown in Figure 1.

The catalogues store information on the schema S1 of the AUTHOR relation. The table AUTHOR contains two tuples for two authors. Then consider the following schema changes:

```
ALTER TABLE AUTHOR
DROP COLUMN PHONE;
ALTER TABLE AUTHOR
ADD COLUMN EMAIL CHAR(30);
```

In this case, the information related to unchanged attributes (i.e., ID, NAME and COUNTRY) are automatically recovered after executing schema changes. The effects of such schema changes are shown in Figure 2.

In particular, we obtain two schema versions, S1 and S2. The new email information could then be introduced through the following SQL statements:

```
UPDATE AUTHOR
SET EMAIL='aicha@author.tn'
WHERE ID = 1;
UPDATE AUTHOR
SET EMAIL='cristiana@author.it'
WHERE ID = 2;
```

Notice that here, without indicating the schema version under which emails should be introduced, the system is able to automatically determine that these new values have to be inserted in the table corresponding to the second version S2 of the AUTHOR relation.

Moreover, since schema versioning supports all schema versions and their underlying data, it (potentially) allows accessing these data, both retrospectively and prospectively, through user

are working, and the physical facet, i.e., the set of class definitions associated to the schema version, which is generated by the DBMS.

Lee et al. (2006) propose a schema version model, titled the extended “Rich Base Schema” (RiBS) model, for restructuring complex object hierarchies. A complex object hierarchy is a set of classes linked between them with reference relationships (which are based on object identifiers), such that one class of them is considered as the root class of the hierarchy and each one of the other classes as a part class of it. In this model, an attribute in a class could be either a leaf attribute, whose domain is a built-in type (e.g., integer, string), or a non-leaf attribute, whose domain is a user-defined class. The authors of the extended RiBS model focus on three aspects: schema evolution operations, query processing, and schema version merging.

Piccioni et al. (2013) propose an IDE-based approach for managing class versioning. More precisely, the authors present a new formal model for class attribute changes, four empirical studies to evaluate the proposed model, a measure of class evolution robustness, and a prototype tool for schema versioning. As for the proposed formal model, the authors deal with schema change operations, class transformations, and object transformers. As for empirical studies, the authors evaluate their model by analyzing four sets of classes written in Java and Eiffel languages while focusing on persistence-related code changes. As for the measure of class evolution robustness, the authors propose “P-Evolution-Robustness” (PER) to measure the robustness of an object-oriented software system with regard to class evolution. PER is defined as a ratio calculated on the basis of transformation functions between class versions. It is applied to all the classes in the “java.util” package. As for the prototype tool, the authors introduce the ESCHER system which implements the proposed model and shows its feasibility. It is integrated into the EiffelStudio IDE, but can also be used as an independent library.

Schema Versioning in XML Databases

D

Baqasah et al. (2013) propose XS-Diff, an algorithm for detecting changes between two XML Schema (or XSD) versions using relational databases. Indeed, XS-Diff starts by parsing and storing the XSD trees corresponding to the two XML Schema versions in relational tables. After that, it applies some specific SQL queries in order to match the identical nodes and store them in temporary tables. Finally, XS-Diff uses the information stored on these tables to generate the set of changes between the two versions and store them in delta tables.

Baqasah et al. (2014) propose an approach for merging XML Schema versions (i.e., XSD files), through the combination of three-way and operational-transformation approaches. Indeed, the authors (i) define a set of rules allowing an automatic three-way XML Schema version merging and conflict resolution, (ii) use transformation functions, in the merging algorithm, for correcting the paths of XSD nodes to be merged, and (iii) develop a merge tool prototype that shows the feasibility and the correctness of the proposed approach.

Malý et al. (2011) extend the framework presented in (Nečaský and Mlýnková 2009), for conceptually modeling XML data based on “Model-Driven Architecture” (MDA) (Miller and Mukerji 2003), to support schema versioning. More precisely, the authors deal with schema change propagation and propose an approach for the revalidation of existing XML documents against any newly created XML schema version. In fact, when a new XML schema version is added, a new version of each XML document, which is valid with respect to the previous schema version, must be correctly generated according to that new schema version. The proposed approach is based on an algorithm which compares the current XML schema version and the new one and returns a revalidation script in XSLT (W3C, 2007). Such a script is applied to the set of XML documents that

are valid with respect to the previous (logically) “modified” schema version in order to produce a set of new versions of the same XML documents, which are valid with respect to the new schema version.

Currim et al. (2009) provide an in-depth and long study on all aspects related to temporal instance versioning and temporal schema versioning in the τ XSchema framework, while presenting all details of the τ XSchema language (including the schema of an annotation document, the schema of a temporal schema document and the schema of a temporal document). Currim et al. (2012) extend such work by focusing on extending conventional XML Schema integrity constraints with temporal semantics, in the τ XSchema framework (Snodgrass et al., 2008) supporting schema versioning. They start by presenting the four types of conventional constraints that are provided by the XML Schema language: datatype, cardinality, identity, and referential integrity constraints. After that, they propose three classes of temporal constraints: (i) sequenced constraints, which are applicable at each point in time, (ii) current constraints, which represent a special kind of sequenced constraints since they are applicable at the current time, and (iii) non-sequenced constraints, which are applicable over a time interval (i.e., a part or the whole of the applicability bound of the constraint) rather than at a point in time. Finally, the authors describe the implementation of their approach (for managing temporal integrity constraints in τ XSchema) through a tool, named τ XMLLINT, which supports all introduced temporal constraints.

Brahmia et al. (2014a) propose a general approach for schema versioning in τ XSchema-based multitemporal XML repositories and deal with all kinds of schema changes (i.e., changes to conventional schema, changes to physical and logical annotations, and updates to the temporal schema) in an integrated environment. In this paper, the authors use their previous work on annotation document versioning (Brahmia et al., 2011) and conventional schema versioning (Brahmia et al., 2012) to provide a complete

figure of their approach for schema versioning in the τ XSchema framework and show, through a running example, how τ XSchema schema could be temporally versioned. The authors also study updates to temporal schema and propose a set of four primitives necessary for updating any temporal schema when its two components or one of them evolves (i.e., conventional schema and/or annotation document).

In order to help designers of τ XSchema schema, and to provide more-user friendly schema change operations that could be easily integrated in tools for XML schema versioning, Brahmia et al. (2014b) propose three sets of high-level operations each one of which is for the maintenance of a distinct component of the τ XSchema schema: forty nine operations acting on conventional schema, fifty-five operations acting on annotation documents, and four operations acting on temporal schema. Notice that a high-level schema change operation is defined as a valid and optimized sequence of schema change primitives (or low-level schema change operations), which expresses a frequent schema evolution need and specifies a complex schema change in a more compact way (Guerrini et al., 2005).

Schema Versioning in Emerging Databases

In the following paragraphs, we present contributions dealing with schema versioning in NoSQL databases.

Castelltort and Laurent (2013) present an approach for versioning graph-oriented NoSQL databases (Robinson et al., 2013). It is based on the following concepts: (i) Data graph: the current version of the graph (also called the operational graph database); (ii) Transaction: a sequence of change operations performed on the data graph in order to update it, while respecting the atomicity property; (iii) Revision: a new version of a graph created after the execution of a transaction; (iv) Version graph: a graph that includes all versions of a data graph (also called the historical graph

database). In this approach, graph versioning is managed as follows: (i) each node (relationship, respectively) in the data graph is represented by a node (relationship, respectively) in the version graph; (ii) to each element (node or relationship) in the data graph, also called trace element, a linked list of revision elements is associated; (iii) each revision element is characterized by (a) all properties of the corresponding element (in the data graph), (b) some useful meta-information (e.g., creation date, creator), and (c) a set for ingoing relationships and a set for outgoing relationships; (iv) each transaction produces a new version graph revision.

Felber et al. (2014) deal with the design and implementation space for providing versioning support on top of a distributed key-value store. They define an API for versioned data access supporting multiple writers and show that a plain key-value store does not offer the necessary synchronization power for implementing this API. They leverage the support for listeners at the key-value store level and propose a general construction for implementing arbitrary types of data structures for storing and querying versioned data. The produced versioning system, ALEPH, is implemented on top of Infinispan, which is an industrial-grade open-source key-value store. The authors evaluate ALEPH under a real workload from Wikipedia access traces.

Wen et al. (2014) introduce Llama, a distributed multi-versioned Model data management architecture to manage the schemata and attributes of structured data in NoSQL databases. In fact, Llama provides solutions for three problems which occur in Supervisory Control and Data Acquisition (SCADA) systems (Carcano et al., 2011) when the Model evolve (notice here that the Model is a set of data to describe the physical topology of monitored devices, including data definitions, device description, device association expression ...): (i) little capacity on schema management of structured data in NoSQL stores, (ii) Model has many versions but changes little, which lead to much unwanted redundancy, and (iii) SQL supported on NoSQL

could lead to a decline in access performance. The authors apply incremental version maintenance and time aggregation compression strategies to reduce the average storage overhead. They claim that Llama reaches the current hot spot version Model with low latency, with it cached in memory and write penetration implemented. Moreover, the authors show, through experimental results, that the average storage overhead is reduced to 20% in Llama, and the read speed of hot spot is more than 10 times faster.

Ruiz et al. (2015) propose a reverse engineering approach to infer the implicit schema of a NoSQL database, while taking into account all the versions of the entities and their relationships. These inferred schemas are named “Versioned Schemas”. Furthermore, the authors also show the usefulness of the inferred versioned schemata through two applications: schema visualization, and automated generation of data validators. Finally, the authors claim that their approach has been validated for three NoSQL DBMSs: MongoDB, CouchDB, and HBase.

DBMS SUPPORT FOR SCHEMA VERSIONING

As far as schema versioning support in conventional DBMSs is concerned, there are no updates that must be made to what we surveyed in (Brahmia et al., 2015). In practice, the only systems that partially provide schema versioning support for XML databases are SQL Server (limited to a subset of XML schema modifications) and IBM DB2 (limited to changes ensuring backward compatibility).

As far as schema versioning support in emerging DBMSs is concerned, Felber et al. (2014) compared versioning support in a set of most used key-value NoSQL systems (i.e., Cassandra, Riak, Couchbase, CouchDB, MongoDB, HBase, Dynamo, and HyperTable). They showed that, although all of them offer support for data versioning and some (i.e., MongoDB with multi-version

concurrency control, HBase, and HyperTable) also allow to maintain complete histories of temporal data versions, none of them provide schema versioning support.

Furthermore, Störl et al. (2015) survey the state-of-the-art of Object-NoSQL Mappers, which are currently used by application developers to deal with schema evolution problems in schema-less NoSQL data stores, since available NoSQL systems do not provide any support for evolving schema of these data stores (notice here that the lack of such a support could be due to the nature of these databases themselves, which are designed to be schema-less or schema flexible). The authors claim that although Object-NoSQL Mappers could manage different versions of objects, these tools do not provide an explicit support for managing schema versions.

FUTURE RESEARCH DIRECTIONS

The open research issues for schema versioning include:

1. Explicit schema versioning support is absent in all commercial systems (i.e., DBMSs and schema management tools), as shown in the previous section. Thus, this aspect needs further efforts in order to provide more efficient practical solutions for database designers and administrators.
2. Schema versioning support is also absent in the standard SQL language. Hence, SQL cannot be used to exploit the potentialities of a relational database supporting schema versioning. Assuming the proliferation of different versions of schema and associated data, suitable extensions to SQL should be defined and implemented in order to allow applications to access data defined under multiple schemas.
3. In a system where different schema versions coexist, the database designer or administrator could need to perform the following tasks:
 - a. To compare some schema versions in order to fulfill some requirements; therefore, comparing two different schema versions to identify the differences could also be an interesting research issue (available research results on schema integration could be adapted to the purpose).
 - b. To migrate data from one schema version to another one dynamically, even when a database continues to accept new data; thus, focusing on tools that could facilitate such a migration would be an interesting research topic which has rarely been addressed.
4. The support of schema versioning could lead to performance degradation due to the proliferation of versions. Thus, further interesting and challenging research topics are (i) efficient techniques to organize data storage spaces and (ii) advanced index structures to optimize data access under schema versioning.
5. Nowadays, many enterprises use Web and distributed databases and, thus, schema changes have to be effected more frequently, since user requirements, laws and technologies change rapidly. Therefore, it will be very interesting and useful to study schema versioning in Web and distributed environments. Among the first works in this area, we find (Rae et al., 2013), which describes techniques used by Google's F1 DBMS (Shute et al., 2013) to support schema evolution in a globally distributed environment.
6. The database provenance is very useful in many modern information systems (like big science projects), in order to explain the lineage of the current data. This explanation often requires "flashing back" to the original schema and, thus, supporting database provenance under schema versioning could be an interesting issue. Although provenance has been studied under schema evolution (Gao & Zaniolo, 2012), to the best of our knowledge, currently there is no work on data provenance under schema versioning.

CONCLUSION

In this chapter, we studied recent advances on schema versioning in traditional and emerging databases, and explored its support in commercial database systems.

Although a lot of work has been done at theoretical level and solutions have been proposed by researchers, there is no efficient practical support for schema versioning at the state-of-the-art of database technology. In order to successfully manage the schema versioning process, the database designer or administrator has to manually convert data defined under the previous schema in order to be valid with respect to the new schema, and the application developer(s) must carefully revise existing applications to support the new schema.

KEY TERMS AND DEFINITIONS

Database Conversion/Migration: Process consisting in adapting data valid under a given schema version to another schema version.

Database Schema: The formal structure of the database, described by means of a data definition language.

Schema Change Propagation: The effects of a schema change at instance level, involving suitable conversions necessary to adapt extant data to the new schema.

Schema Change Semantics: The effects of a schema change at schema level.

Schema Changes: Operations performed on a (populated) database schema, in order to adapt it to new application requirements.

Schema Evolution: A schema change modality that avoids the loss of extant data. No support is required for previous schemata.

Schema Version: A complete database schema as created by the initial design or by the application of schema changes to an existing schema.

Schema Versioning: A schema change modality that provides for the maintenance of previous schema versions, such that extant data are accessible through any of the supported schema versions.

Temporal Database: A database with built-in support for managing time-varying data.

Temporal Schema Versioning: Schema versioning technique, in which different schema versions are indexed by timestamps.

Twitter Data Mining for Situational Awareness

Gian Luca Foresti

University of Udine, Italy

INTRODUCTION

The most recent catastrophic events, from the 2010 Haiti earthquake to the devastating 2013 Colorado floods, have shown a strong adoption of social media platforms by ordinary people. The data and meta-data produced by users during and after extra-ordinary situations could have enormous potentialities if integrated with traditional systems for emergency management and used for hyperlocal situational awareness (Foresti et al., 2015a). The great majority of current literature is focused on Twitter for several reasons, in particular, the architectures and practices of the platform itself. In the following section, an overview of social media use in extra-ordinary contexts will be presented, with a specific focus on the Twitter social media platform. Following this, in a section dedicated to the Twitter systems classification for situational awareness, a classification of the existing systems based on the analysis of Twitter data will be provided on the basis of the following three categories: 1) semantic systems; 2) meta-data systems; and 3) smart self-learning systems. Finally, in the future research trends section, an innovative and smart solution will be proposed for future development.

BACKGROUND

Social Media Use in Extra-Ordinary Contexts

Social media platforms are built from the beginning to be used socially, and oriented around collaboration and sharing. These potentialities are emphasized in extra-ordinary contexts, when ordinary people adopt these tools to provide or search for first-hand and real-time information regarding a certain event (i.e. an earthquake, flood, etc.) (Lindsay, 2011; Taylor et al., 2012). The most recent catastrophic events, from the 2010 Haiti earthquake to the devastating 2013 Colorado floods, in fact, have shown that these platforms have been strongly used both during and after disasters (Figure 1), allowing a real-time dissemination of information to the wider public, an effective situational awareness, and an up-to-date picture of what is happening on the ground (i.e. Farinosi & Micalizzi, 2013; White et al., 2014).

According to Kotsiopoulos (2014), in extra-ordinary situations, social media enable citizens to play at least three roles: 1) first responders/volunteers; 2) citizen journalists/reporters; and 3) social activists. Oftentimes citizens on the scene experience the event first-hand and are able to

provide updates more quickly than disaster response organizations and traditional news media (Sweetser & Metzgar, 2007; Procopio & Procopio, 2007; Farinosi & Micalizzi, 2013).

Given the increasing availability of data and meta-data produced and/or distributed on these online platforms, it is pivotal to understand how they should be used and integrated with traditional systems for situational awareness, supporting in this way the work of Civil Protection, Red Cross, Fire Department, and other agencies.

A Focus on Twitter

The great majority of existing research is focused on the social media platform Twitter. Twitter is a popular microblogging network that allow users to share up to 140 character text messages called tweets. Twitter was founded in 2006 by Jack Dorsey, Evan Williams, Biz Stone, and Noah Glass. Today it is one of the most used social platforms with about 250 million active users and about 500 million tweets shared per day (source: <https://dev.twitter.com/>). The platform is mainly based on the exchange of messages between networks of contacts. Each user can create his/her own custom networks, following other users' feeds. In turn, each user can be followed by other users called followers (Marwick and Boyd, 2011). Besides the possibility to share a short text content, Twitter also offers the opportunity to share visual content, such as videos and images, and URLs to web sites (Java et al., 2007; Huberman et al., 2008; Zhao & Rosson, 2009).

The reason why the majority of research is focused on Twitter is due to many factors. First of all, given the instantaneous nature of communication on Twitter, the platform is particularly suitable for real-time communication. Furthermore, the architecture and some specific features of Twitter seem to facilitate the widespread dissemination of information. Among the most important features offered by the Twitter platform is the possibility to share content using hashtags. This is an annotation format represented by the “#” symbol, used to

indicate with a single word (or a combination of words) the core meaning of a tweet. Conversations centered on specific hashtags promote focused discussions, even among people who are not in direct contact with each other.

In addition, the choice to analyze Twitter is also motivated by the prevailing public nature of the great majority of the accounts (only a small percentage of accounts are private), a feature that distinguishes this platform to other social networking sites (Bruns & Burgess, 2013). On the one hand, this peculiarity promotes public conversations, even among users that were not previously in contact with one another (Twitter in fact offers the possibility to interact with other users, to share content with them, and to reply or mention someone in your own tweet simply using the symbol “@” followed by the username of the person whom you want to tag). On the other hand, it makes it easier to conduct analysis that aims to reconstruct the spread of communication flows within the platform. Finally, yet importantly, this characteristic makes the use of tweets for research purposes less critical from an ethical point of view.

For example, the analysis of the 2011 floods in Queensland provides a detailed mapping of the general dynamics of Twitter use during an emergency and offers useful general indications (Bruns, 2012). Their findings highlight that the space-time variables represent a crucial element to obtain relevant data and to improve situational awareness during disasters. For instance, the physical distance of the Twitter users from the site of the catastrophe can reflect different types of needs to be met and a different perception of danger. In addition, given that a social platform like Twitter is structurally connected to forms of activation just in time, the time variable plays a fundamental role. Previous research demonstrates that immediately after the event there is a greater presence of forms of instinctive response, while tweets containing links to official news sources tend to arrive later (Acar & Muraki, 2011; Farinosi & Micalizzi, 2013).

Figure 1. An example of tweets posted on Twitter during the 2013 Wellington earthquake

DATA MINING ON TWITTER

Tweet data extraction operations involve the use of suitable API libraries, which provide all the tools and services to retrieve user tweets and their correlated information.

When a user posts a tweet on Twitter, besides the text content of 140 characters, he/she can share other useful information such as videos, images or GPS coordinates. Considering a given emergency event, this information could be useful to accurately locate the area where the event is occurring and to better coordinate rescue operations.

In the state-of-the-art there are several APIs (Application Programming Interfaces) which provide useful tools to collect and analyze tweets shared by users. In general, it is possible to dis-

tinguish official Twitter libraries and unofficial libraries created for specific programming languages (i.e. Neo4J source: <http://neo4j.com/>). Usually the unofficial libraries use the core libraries of the Twitter APIs to retrieve data from the Twitter server but are customized for specific purposes.

Twitter APIs are the official programming libraries proposed by Twitter (source: <https://dev.twitter.com/>). These APIs allow different type of operations to be performed such as the extraction of tweets from Twitter streams or creation of custom applications for websites. They are freely available although they can be used with some limitations (see “Twitter APIs limitations” section).

Twitter APIs can be generally classified into four groups: 1) Twitter for Websites, 2) Search APIs, 3) REST APIs, and 4) Streaming APIs.

Twitter APIs Limitations

Twitter APIs are freely available for the creation of custom applications with the goal of analyzing Twitter stream data and extracting useful information.

Nevertheless, APIs have certain limitations. First, there is a restriction regarding the number of requests that can be sent to Twitter servers. For example, if you want to extract data of a specific user (e.g. information about the profile of the user, his/her tweets etc.) or simply to collect tweets containing a specific keyword, it is only possible to send 180 requests every 15 minutes. If the maximum limit is reached, then the system automatically discards the following requests until the time window of 15 minutes has elapsed.

Moreover, there are other limitations regarding the use of Twitter APIs. For example, considering Streaming APIs, only a random sample corresponding to 1% of the total tweets is retrieved from Twitter stream data. This means that some relevant information could be missed during the harvesting process.

Furthermore, the REST APIs have some limitations. They do not provide access to tweets up to about a week old. Moreover, only tweets posted from public Twitter profiles can be retrieved, collected, and analyzed.

TWITTER SYSTEM CLASSIFICATION FOR SITUATIONAL AWARENESS

In the literature, there are many significant studies exploiting the use of Twitter to locate and analyze in real-time a given event for situational awareness. In particular, these systems are able to extract and save tweets from Twitter streams and analyze them with the goal to collect useful information. All these systems are very similar to each other, although they can be classified into three main groups on the basis of their characteristics:

1. Semantic systems, based on a textual analysis of the content;
2. Meta-data systems, based on the extraction of meta-data information;
3. Smart self-learning systems, able to identify in real-time a trending topic and to automatically search other secondary hashtags connected to the initial one.

Regarding the semantic systems focusing on situational awareness (Figure 2), this kind of application is characterized by the possibility to analyze the textual content of the tweets written and shared online by Twitter users. In several cases, the tweets posted by users could be very useful to identify relevant topics of discussion and, in doing so, to detect specific contextual information (i.e. collapsed buildings or numbers of wounded, dead, etc.). The first example of semantic systems is identified by Corvey et al. (2012) who are able to extract linguistic and behavioral information from tweet text to aid in the task of information integration. Through linguistic annotation, in the form of Named Entity Tagging and behavioral annotations, it captures tweets and then analyses and classifies their content, contributing to situational awareness. Another interesting example of this kind of system is that developed by Schulz et al. (2012), which uses crowdsourcing and Linked Open Data to enhance, classify, and filter the information shared by people on social media (i.e. Twitter or Facebook). This results in a structured dataset that contributes to the identification of a certain event.

A third example can be identified in the system implemented by Zielinski et al. (2012), which is able to analyze multilingual Twitter feeds for emergency events. Exploring the number of tweets posted online before and after ten earthquakes in the Mediterranean area, it detects a disaster by observing a rapid increase in Twitter, focusing in particular on posts written in the native language of the area hit by the seism.

Figure 2. An example of a system to extract data from Twitter stream during an emergency event

It is worth mentioning also the system developed by Klein et al. (2012), a Twitter crawler that analyzes the stream through a combined social and content-aware analysis approach. It conducts a grammatical analysis in order to classify the textual content of tweets in nouns, verbs, adjectives, etc. and groups single words in meaningful units, extracting in this way knowledge from texts through named entity recognition algorithms. By querying the Twitter Streaming API with ad hoc keywords focused on the specific disaster and the location, it is able to detect emergencies in real-time.

Another example of a tool that can be employed for situational awareness, even if originally conceived for a broader purpose, is Eddi, an interactive topic-based browser for Twitter feeds. It allows for the organization of tweets on the basis of specific topics (e.g. a crisis event or political elections, etc.) making their visualization more feasible. It provides different features: 1) a tag cloud overview for showing major topics, each of which is scaled proportionally to the number of tweets assigned to it; 2) a topic detail view, available by clicking

on each tag, provides a view of all tweets about a specific topic; 3) navigation list, that contains a complete list of the feed's topics sorted by popularity; 4) topic dashboard for displaying an overview of the most interesting topics that the user might like; and 5) a timeline that focuses on the temporal factor, stressing on spikes and trends over time. Among the possible contexts of use, Eddi could be adopted during and after a natural disaster to identify trending topics of discussion and relevant content of tweets.

Regarding the meta-data systems (Figure 2), these kinds of applications are able to use and aggregate different types of data. As for the semantic systems, they are able to extract and analyze the textual content of tweets related to a certain event, however, they also take into account other types of data directly produced by the social platform itself, such as time and date of the tweet, GPS coordinates, URLs shared, and so on. Twitcident (Abel et al., 2012), is the first example of a meta-data system. This is a framework and web-based system that is automatically able to filter, search, and analyze tweets about real-world incidents,

crises or natural hazards. Adopting semantic filtering strategies including tweet classification, named entity recognition, and linkage to related external online resources, it monitors emergency broadcasting services and automatically collects and filters tweets whenever an incident occurs.

The core of Twitcident is composed of several modules: 1) Incident detection module, which is able to identify incidents employing the P2000 communication network, an ad hoc broadcasting service used in The Netherlands by Police and other emergency operators. Whenever an incident is detected, the collected messages are semantically analyzed by the 2) Semantic enrichment module. This identifies the tweets relevant to a given incident and performs a real-time analysis. Twitcident also collects additional meta-data about the publisher of a tweet, his/her profile picture, number of followers, his/her location when publishing the tweet etc. All these data are useful to assess the trustworthiness of a tweet and improve the reliability of the whole system.

Another system for supporting emergency planning and risk assessment activities that also takes into account meta-data was developed by De Longueville (2009). This project analyzed the activity of Twitter users during a fire that broke out in Marseille in July 2009 through the Twitter's API and a search of the keywords "incendie" and "Marseille". They classified the content on the basis of the users and identified three major roles: citizens, media, and aggregators. This last category did not generate primary content but distributed existing sources (i.e. news produced by citizen journalists) through abbreviated URLs to blogs, news portals, and picture websites such as Flickr and Twitpic. It is worth noting also TEDAS (Rui Li et al., 2012), a system which uses keywords and GPS coordinates to discover spatial and temporal patterns of events, and the region of major influence. The high coverage of Twitter users, along with the rich information associated to tweets, allows TEDAS monitor events in a fast and accurate way. It is able to recognize new events, rank them according to their importance, and generate

a spatial-temporal pattern for any event. The tool takes a query, which contains keywords, a temporal period, and a location and extrapolates relevant tweets. Furthermore, it identifies and classifies tweets based on some relevant keywords, giving more relevance to those posted by an authority.

Another interesting system has been developed by Sakaki et al. (2010). Through the analysis of tweets and keywords (e.g. "earthquake" or "shake"), it is able to automatically detect target events and send notifications promptly to those who are registered. Moreover, the system applies Kalman and particle filtering in order to detect accurately the location of the event.

It is worth mentioning also a tool created to enhance the situational awareness in emergency events which uses Twitter Search APIs to find tweets through a query of case-insensitive terms and then analyses textual data, GPS-coordinates, and the registered location of the tweets, and visualizes their content by the E-Data Viewer (EDV) (Vieweg et al., 2010). A more specific system for disaster response is that developed to help relief workers during natural disasters (Ashktorab et al., 2014). It adopts different methods (i.e. sLDA, SVM) to classify in real-time the material shared from areas close to the disaster location and extracts the most relevant phrases about structural and infrastructural damage.

A similar system has been developed by Walther and Kaiser (2013). This is able to detect geo-spatial real-world events in real-time. It focuses on clusters of Tweets sent in a short time span and stores them for at least 48 hours in an open-source database (MangoDB). Then - through a Machine Learning component, which uses 41 features that address several of their aspects - the material is analyzed and filtered in order to eliminate tweets generated from bots or false positives.

For what concerns the last category, it refers to smart self-learning systems (Figure 3), and includes those applications able to identify in real-time a location affected by a certain event combining characteristics used by semantic and meta-data systems.

Figure 3. An example of smart self-learning system

However, in contrast to the previous categories, they are also able to self-learn from the content of tweets analyzed, identifying the most adopted words and hashtags and automatically looking for other secondary hashtags connected to the first ones. A first example of these systems is CrisisLex (Olteanu et al., 2014). The aim of this system is to improve the query to the Twitter servers in order to harvest the most relevant tweets during a specific crisis. As a first stage, the system creates a lexicon of crisis-related terms that frequently appear in relevant messages posted during different types of past crisis situations. The lexicon is then used by the system to automatically identify new terms that describe a given crisis. Moreover, it allows the automatization of the choice of keywords contained in the tweets. Data collection is optimized using keywords or geo-location searches. CrisisLex constitutes a first attempt to develop a smart self-learning system. Further research is needed to develop more accurate systems able to identify specific areas where the event is occurring, extracting only the data related to that event in that area.

In the next section, a possible innovative smart solution will be illustrated.

FUTURE RESEARCH TRENDS

As presented in the previous section, a lot of systems that collect and analyze in real-time data from Twitter to extract useful information of a given event already exist in the literature. They are mainly based on the semantic analysis of the text content of the tweets or on the analysis of meta-data linked to the tweets, such as the URLs shared by Twitter users or GPS coordinates. Even if this kind of system is able to analyze Twitter streams in real-time, future research will aim to develop more intelligent architecture integrating different types of data shared on Twitter by ordinary people during an event (Foresti et al., 2015b). Such a system should be able to extract data that are as accurate as possible both as regards the semantic analysis and the GPS location. When a certain event happens, the system could automatically detect the geographic area where it is occurring

with the goal to extract only the relevant information related to the event itself. For this purpose, state-of-the-art clustering algorithms could be used to identify and correctly classify the different events. The system should be able to consider several parameters such as the number of tweets shared by users in a certain lapse of time, and to compare them to the density of the population of the specific area, automatically recognizing if a certain event is happening or not. Another important feature which could be investigated in future research is automatic trend hashtags identification with the aim to improve situational awareness. The hashtag is an annotation format used on Twitter to indicate the topic of a tweet through one or more specific keywords. Nevertheless, when a crisis situation occurs, the hashtags adopted by Twitter users could be manifold, each one with a specific meaning. Therefore, the system should be able to classify hashtags considering their importance and use them to optimize future research on a given event. A solution could be the use of an automatic algorithm which gets as input all the hashtags adopted by the users to spread the event, and classifying them by keeping account of only the most relevant ones. Then, the identified hashtags could be used as input for future research with the main goal of optimizing them and also training the system.

Moreover, another feature that could be implemented to enhance rescue operations is the analysis of images posted by users on Twitter. In this way, future systems might be able to take into account not only textual data or meta-data, but also visual data uploaded by people and distributed on social media platforms. This visual information represents a useful resource, especially when it is linked to GPS coordinates, given that it means the possibility to detect in real time a hyperlocal situation and obtain a detailed picture of a certain location. The system should be able to automatically compare the visual content with other kinds of images (i.e. pictures from Google Earth), providing emergency operators real time

remote monitoring of the situation and highlighting critical points that require action.

D

CONCLUSION

In this contribution, the most important systems based on Twitter data mining have been classified into three different groups: 1) semantic systems, which are based on a textual analysis of the content; 2) meta-data systems, based on the extraction of meta-data information; and finally 3) smart self-learning systems, able to identify in real-time a trending topic and automatically look for other secondary hashtags connected to the initial one. The analyzed literature shows that there are a large number of systems able to detect and analyze different kind of crisis events. Nevertheless, nowadays there are only a few systems based on an effective real-time identification of an event and it would be really useful to improve the algorithms able to self-learn from previous events. For this purpose, in the section “future research trends”, potential new applications to enhance smart self-learning systems have been proposed. In the future such systems exploiting grassroots data generated and spread by citizens on the scene of disasters will gain a strategic role in emergency management and provide strong support to institutional operators.

KEY TERMS AND DEFINITIONS

Data Mining: A computational process of discovering patterns in large data sets. The main goal is to extract knowledge from a data set and transform it into an understandable structure for further use (i.e. machine learning or predictive analytics).

Hashtag: Annotation format represented by the “#” symbol, used to indicate with a single word (or a combination of words) the core meaning of a tweet.

Meta-Data: Data providing information about a certain item’s content. For example, a tweet may include meta-data specifying GPS coordinates, or information about when it was sent, by who, and so on, which can be analyzed to extract meaningful information.

Situation Awareness: Pre-requisite state of knowledge and cognition of events useful for making decisions in situations involving uncertainty and crisis.

Tweet: Message posted on Twitter which may contain up to 140 characters of text, photos, videos, links, and so on.

Twitter APIs: A set of software libraries used by developers to extract data from Twitter streams. Twitter provides different types of software libraries (e.g. REST APIs, Streaming APIs, etc.), each one with its own specific function.

Web Crawler: Software program able to automatically analyze the content of web pages in order to recognize useful information.

Decision Support Systems

Cognitive Process Elements of People Decision-Making

Thais Spiegel

Rio de Janeiro State University, Brazil

INTRODUCTION

With computers and the interest in information processing, a new image of man begins to emerge. In the 1950s, studies of Broadbent (1954), continuing the Cherry (1953) model, culminate in the model of human thought processes. A model that began with the information received by the senses, but concentrated on a new and important feature: the individual has a limited capacity for receiving and storing information (Gardner, 2003).

These results were related to the work of George Miller. Miller (1956) in “The magical number seven, plus or minus two: some limits on our capacity for processing information”, when referring to classification and coding, indicates that there are limitations to the ability to process sensory signals on the order of about seven. At the same time, Bruner led the “Cognition Project” at Harvard. Faced with the observations of human performance in tasks of formation and acquisition of concepts, Bruner, Goodnow and Austin (1956) suggest that individuals suffered a state of “cognitive strain” and tried to reduce it through strategies of simplification.

In the study of decision-making, the classical view of behavioral appropriateness or rationality was also challenged by psychological reasons. One major example was Simon’s theory (1957) of “bounded rationality”, in which it is proposed that cognitive limitations lead decision-makers to construct simplified models for dealing with the world. In the same study, Simon (1957) suggests several cognitive strategies, the average, the sum and subtraction, to explain the behavior of different economic agents. The best known example is the

“satisfaction” one, which explains the behavior of consumers looking for a “good enough” option in an uncertain environment, where the search for alternatives is costly. To satisfy is a heuristic decision which involves choosing the first alternative that meets its minimum requirements. To satisfy is simple in terms of cognitive operators; therefore it makes smaller demands to the scarce mental resources. However, it can lead to sub-optimal behavior, given that finding an acceptable option, the search and evaluation of other alternatives, possibly better ones, ceases.

When asked by Gigerenzer about why bounded rationality is not the same as irrationality, Simon responded with an analogy. “Bounded rationality is like scissors: the mind is a blade and the structure of the environment is the other blade. To understand the behavior, we have to look at both and in how they fit.” (Simon, 1990:7 *apud* Gigerenzer, 2004:397). In other words, in order to assess the cognitive strategies as rational or irrational, one must also consider the environment because a strategy is rational or irrational only with respect to a physical or social environment (Simon, 1990). Thus, models of bounded rationality bring the reality and consider how human with little time and knowledge behave. This term, coined by Simon (1955) is associated with three distinct programs: the study of optimization under constraints, the study of cognitive illusions and the study of fast and frugal heuristics.

In the search for descriptions that adhere more closely to the human decision-making process, this text briefly contextualizes the human perspective in the study of decision-making. It then proceeds, on the basis of a review of the literature

on cognition during decision-making, to propose the formulation of a model that identifies the roles of aspects of cognition, and their inter-relations, during the decision-making process.

BACKGROUND

Some models of decision-making involved in descriptive approaches, approximating to how decisions are really taken. In the heuristics and biases program, the focus is on the individual's process to reach a conclusion, i.e. in the judgment that leads to the decision. It can be said that the central input is to indicate the existence of particular types of processing, covering certain areas in greater or lesser extent, and that in their function there is a set of trends in decisions made. It is relevant to point out that people do not decide rationally. It refers to a set of evidences of bounded rationality and systematic deviation from the optimal model, the expected decisions. However, it fails to explain why the heuristics manifest, how they operate in cognitive terms.

The program of fast and frugal heuristics is particularly interesting as it locates individuals in the context, and considers the rooted empirical knowledge that they have. With the ecological rationality reinforces the kinds of decision-making process before which the heuristic, of specific domain, change. This direction to the context is done without losing the object of analysis - the decision-maker. It goes on, however, without explaining how the cognitive process works. Explanations relating the types of environments with cognitive functions are not formulated, for example.

The dual processing models advance in attempts to explain the processing operation "within" the individual's head. They contribute, fundamentally, to mark the existence of non-rational processes, guided by intuition. It is also important to strengthen processes under which people have no control and awareness. It features a large contribution, which goes toward closer

cognitive processes. It remains, however, without explanation as to the correlation between the actual functioning of processes and the types of problems that are presented to individuals.

With cognitive models, the advance continues, recognizing structures formed by individuals that make up their understanding, assessment, and access or not to certain information and previous experiences. Particular aspects of each individual are emphasized as attention focuses on the formation of "schemes", which carry the history of the decision-maker.

The ramifications of this study lead to sense-making, through which one has contact with the attribution of meaning, and reinforces the unconscious processes. The concept of the production of retrospective explanations is of great contribution to the Decision Theory. The existence of the framing phenomenon commands researchers' attention to variations that cause information to be better or worse perceived and evaluated. The existence of a coding process in information processing that shapes the perception of the value of information is evidenced in this theoretical framework.

However, advances in the understanding of the cognitive process have been partly incorporated into organizational applications. Although cognition figures among the earliest focuses for research (Thagard et al., 2007), it is still a subject with many open questions in all the fields where it is considered. Very recently (as compared with other fields) organization-related inquiries entered this group of interested parties (Spiegel, 2013).

In order to understand decision-making "completely", and improve it, the underlying decision-making processes and the variables that affect the process must be examined (Roberts, 2002). Ola Svenson writes: "Human decision making cannot be understood simply by studying final decisions. The perceptual, emotional, and *cognitive* process which ultimately lead to the choice of a decision alternative must also be studied if we want to gain an adequate understanding of human decision making." (Svenson, 1979 apud Roberts, 2002, p.6)

Figure 1. Relationship among the roles of elements of cognition
 Source: Spiegel (2014).

On this question, Simon (1985, p.303) argues that: “Nothing is more fundamental in setting our research agenda and informing our research methods than our view of the nature of the human beings whose behavior we are studying”. Even when the focus is the outcome of the decision-making, ultimately it is the process that leads to it and allows it to be defined. While previous research was concerned with decision-making inputs and outputs, attention is now shifting to probe inside the “black box”, to examine the real processes involved in generating results from inputs (Roberts, 2002).

In that context, the hypothesis of this study is that the understanding of decision-making agents’ cognitive processes gives the basis necessary for understanding their decisions better. Once they are understood, that is believed to give access to the foundation underpinning description of human decisions (Spiegel, 2014).

MAIN FOCUS

Given the importance of opening the “black box”, this article presents the results of a review of the

related literature. It offers a structured presentation of the present state of our understanding of how cognition functions, and of its roles in relation to decision-making. From the literature, five elements - attention, consciousness, categorization, memory and emotion - were identified as representative aspects of cognition for understanding the decision-making process. In the search and model conception process, it was decided to work with consciousness as an element cross cutting the others. Accordingly, the state of (un)consciousness during the manifestation of the other aspects will be addressed when discussing the roles involved. Figure 1 summarizes the roles identified in the review presented in Spiegel (2014).

Table 1 summarizes an enhanced of the roles identified in the review presented in Spiegel (2014).

Below, a brief summary is given of the model constructed in the light of the roles set out in Spiegel (2014). Attention acts to selecting stimuli from the external and internal environments, and is limited by memory capacity, which acts to restrict information acquisition. Decision makers’ perceptions are shaped by their storage capacity and guided by emotional mechanisms “activated”

Table 1. Summary of roles played by elements of cognition

Cognition Role		Relevant Sources
Attention	Attention as selection, preparation and maintenance: determines initial perception of the problem	LaBerge (1999); Lachter et al. (2004); Posner & Rothbart (2007); Weber & Johnson (2009); Nejad (2014).
Categorization	Categorization as the basis for recognizing the situation: storage of the characteristics and the reconstitution	Kahneman & Tversky (2000); Miller & Cohen (2001); Cree & McRae (2003). Barsalou (2003, 2005); Cohen & Lefebvre (2005); Damásio (2005); Thagard et al. (2007).
	Categorization as the basis for situating perceptions	Smith et al. (2004); Barsalou (2003, 2005); Kourtzi (2010); McNamee, Rangel, O'Doherty (2013).
	Categorization as the basis for inferring about the problem	Barsalou (2005); McNamee, Rangel, O'Doherty (2013).
Memory	Memory as information source	Guenther (2002); Roberts (2002); Gonzalez (2013); Gutzwiller & Clegg (2013).
	Memory as constraint on information acquisition	Kareev et al. (1997); Rakow et al. (2010); Gutzwiller & Clegg (2013).
	Memory as bases for rapid perception, making for an agile decision-making process	Gupta et al. (2009); Gonzalez (2013); Gutzwiller & Clegg (2013).
Emotion	Emotion as information source	Mellers (2000); Slovic et al. (2002); Schwarz (2002); Pfister & Böhm (2008); Sun & Mathews (2012).
	Emotion in steering attention to important aspects of the problem	Berthoz (2006); Peters (2006); Pfister & Böhm (2008); Weber & Johnson (2009), Lerner et al. (2015).
	Emotion with a role in speed, permitting quick decisions when time is short	Bechara et al. (1997); Damásio (2005); Thagard et al. (2007), Brosch et al. (2013).

Source: Enhanced Spiegel (2014).

in the presence of the stimuli. Attention mechanisms bring not only accuracy, but also speed, to perception, preparing the system for information processing. In a manner integrated with the categorization process, in some situations, processing is accompanied by the maintenance of attention to certain stimuli.

In addition to this perceived information, which is discussed in the traditional decision-making literature, this present study emphasizes the importance of the decision maker's memory and emotions as conscious or subconscious sources of information. Emotional experiences at the various different stages of the decision-making process distinguished by Loewenstein & Lerner (2003) play a valuable role for decision makers, leaving them ready to react with pleasure or displeasure to the courses to be taken. It must be stressed that the experiences they are subjected to previously are critical here.

Returning to the internal or external stimuli, consciously or not, categorization plays a promi-

nent role by confronting them with patterns, enabling decision makers to recognize situations, which entails dimensions of storage, but also mental reconstitution, through mechanisms for simulating the experienced situation. The way the situation is presented activates distinct mechanisms with specific modes with regard to the role of categorization as situated perception, unlike interpretations by single mechanism acting in a decontextualized fashion.

The stored situations and subsequent simulations create a basis in categorization for inferences about problems. They thus speed the decision-making process. Memory and emotion as an information source are important influences in bringing greater agility to decision making. As information sources, these mechanisms, by establishing emotional relationships and reinforcement cycles in access to stored information, automate some steps of processing.

FUTURE RESEARCH DIRECTIONS

Future initiatives within the role of cognition in decision making include the answers that are observed whenever people face decisions from the experience and the description. The fact of the information that is relevant for the decision be necessarily built over the time, makes the decisions from the experience to be a good way to explore the sequential information processing (Barron & Leider, 2010). In addition, the “wealth” of the paradigm of decision from the experience with its focus on the acquisition and integration of information previous to the choice as well as the act of the choice, is available to more complete investigations in the individual differences in the cognitive processes (Rakow & Newell, 2010).

It became evident in the behavioral decision literature that these different approaches for the experimental study of decision-making, differ not only in the nature of the information provided but also in the way the acquired information is used to guide decisions (Hertwig *et al.*, 2004). In spite of this growing behavioral evidence, neurobiological studies of decision-making, haven’t been able to solve the way the differences of presentation may potentially influence the neural representations underlying these variables (Jessup & O’Doherty, 2010). Results indicate the decision variables generated based on the specific provision of descriptive information are not processed neurally the same way the decision variables acquired based on learning by trial and error. It’s important notice, that the brain systems identified in the two different conditions are not likely to be exclusively involved in one or other kind of decision-making (Barron & Leider, 2010). For instance, it was identified in other researches that the prefrontal cortex ventromedial represents decision values also under conditions that involves the providing of descriptive information. While MRI studies have found there is correlation of the activity in the ventral striatum with the prediction errors, a key sign to play a role in the learning by trial and error, and particularly in the associations between stimulus-result. A similar history is valid for risk

signs in the anterior insula and anterior cingulated (Chib *et al.*, 2009).

CONCLUSION

The decision-making study has as a target the understanding of the human ability of process multiple alternatives and choose an action course. Given the importance of decision makers in decision making, as examined in this chapter, these final remarks are intended to stress this aspect and to attest to the relevance of the contribution of the model formulated to yield descriptions closer to the realities of decision. The problem’s perception and/or the responsibility attribution by the resolution the decision-maker’s responsibility. The decision-maker is the individual or group on who lays the responsibility of dealing with the presented problem and, therefore, some fundamental factors linked to them change the way of how the decision occurs. The number of decision-makers, as well as the quality and the personal preference, defines the solution of the decision-making process.

Decisions are not equal and neither have the same difficulty degree, but they are all dependent on the mental model of their decision-makers. The agents may be evaluated by their individual knowledge about the problem, the resolution ability of each one of them, their desires and interests and the ethical and moral standards that guide them. Recognize the variety among the decision-makers is also necessary, since the performance will be determined by the adjustment of the tasks’ demands with the capacity, knowledge and the willingness to use effort of the decision-maker.

This chapter contributes to the body of knowledge on the subject by identifying and describing four elements of cognition that are representative for the human *decision-making* process. These elements interact, which also conditions the way the *decision-making* process occurs. Figure 1 shows the relationship among the “roles” of *attention*, *categorization*, *memory* and *emotion* over the course of *decision-making*.

KEY TERMS AND DEFINITIONS

Attention: Attention refers to the ability of the individual to respond predominantly stimuli that are significant to the detriment of others.

Categorization: Categorization is the mental operation by which the brain classifies objects and events, comes the ability to group sensory events into meaningful categories.

Cognition: The concept of cognition comes to all capture processes of external stimuli through sensory resources and processing, reduction, storage, retrieval and use of these stimuli.

Consciousness: Consciousness is associated with the ability of human beings to get information itself, as well as get other people and objects.

Decision: The decision-making is understood as the deliberate choice of a course of action with the intention of producing a desired result.

Emotion: Emotions are mental operations are accompanied by a previous experience, capable of guiding the behavior and conduct physiological adaptations necessary.

Memory: The memory comprises a number of biological strategies and anatomical substrates; involves a complex mechanism that covers the storage and retrieval of experiences thus is closely associated with learning.

Comprehensible Explanation of Predictive Models

D

Marko Robnik-Šikonja
University of Ljubljana, Slovenia

INTRODUCTION

In many areas where machine learning methods are applied the practitioners and users of produced prediction models are interested in comprehensible explanation of their predictions. Unfortunately, the best performing predictive models do not offer an intrinsic introspection into their decision processes or provide explanations of their prediction. This is true for Support Vector Machines (SVM), Artificial Neural Networks (ANN), and all ensemble methods (for example, boosting, random forests, bagging, stacking and multiple adaptive regression splines). Approaches that do offer an intrinsic introspection such as decision trees or decision rules do not perform so well or are not applicable in many cases (Meyer et al., 2003). The areas where models' transparency is of crucial importance are for example most of business and marketing applications where the executives are just as interested in the comprehension of the decision process, explanation of the existing and new customers' needs and expectations in a given business case, as in the classification accuracy of the prediction model. The same is true for many areas of business intelligence, finance, marketing, insurance, medicine, science, policy making, and strategic planning where knowledge discovery dominates prediction accuracy.

To alleviate this problem two types of solutions have been proposed. The first type is based on internal working of each particular learning algorithm and exploits its learning process to gain insight into the presumptions, biases and reasoning leading to final decisions. A well-known example of such an approach are random forests for which several

visualizations exist mostly exploiting the fact that during bootstrap sampling some of the instances are not selected for learning and can serve as an internal validation set. With the help of this set important features can be identified and similarity between objects can be measured. The second type of explanation approaches are general and can be applied to any predictive model. Examples of this approach are methods EXPLAIN (Robnik-Šikonja & Kononenko, 2008) and IME (Štrumbelj et al., 2009). These two methods are based on efficient implementation of input perturbations. They can explain models' decision process for each individual predicted instance as well as the model as a whole. As both methods are efficient, offer comprehensible explanations, can be visualized, and are readily available in R package ExplainPrediction (Robnik-Šikonja, 2015) they are the focus of this article. Other general explanation methods are discussed in the background Section.

The objective of the article is to explain how EXPLAIN and IME explanation methods work and to show their practical utility in several real world scenarios. The first aim is achieved through explanation of their working principle and graphical explanation of models' decisions on a well-known data set. Two types of explanations are demonstrated, predictions of new unlabeled cases and the functioning of the model as a whole. This allows inspection, comparison, and visualization of otherwise opaque models. The practical utility of the methodology is demonstrated with short description of several applications: in medicine (Štrumbelj et al. 2010), macro economy (Pregeljc et al., 2012) and business consultancy (Bohanec et al., 2015).

DOI: 10.4018/978-1-5225-2255-3.ch181

BACKGROUND

In a typical data science problem setting, users are concerned with both prediction accuracy and the interpretability of the prediction model. Complex models have potentially higher accuracy but are more difficult to interpret. This can be alleviated either by sacrificing some prediction accuracy for a more transparent model or by using an explanation method that improves the interpretability of the model. Explaining predictions is straightforward for symbolic models such as decision trees, decision rules, and inductive logic programming, where the models give an overall transparent knowledge in a symbolic form. Therefore, to obtain the explanations of predictions, one simply has to read the rules in the corresponding model. Whether such an explanation is comprehensive in the case of large trees and rule sets is questionable.

For non-symbolic models there are no such straightforward explanations. A lot of effort has been invested into increasing the interpretability of complex models. A taxonomy of explanation methods and a review of neural network explanation approaches is given by Jacobsson (2005). For Support Vector Machines an interesting approach is proposed by Hamel (2006). Many approaches exploit the essential property of additive classifiers to provide more comprehensible explanations and visualizations, e.g., (Jakulin et al., 2005) and (Poulin et al. 2006).

Visualization of decision boundaries is an important aspect of model transparency. Barbosa et al. (2016) present a technique to visualize how the kernel embeds data into a high-dimensional feature space. With their Kelp method they visualize how kernel choice affects neighborhood structure and SVM decision boundaries. Schultz et al. (2015) propose a general framework for visualization of classifiers via dimensionality reduction. Goldstein et al. (2015) propose another useful visualization tool for classifiers that can produce individual conditional expectation plots, graphing the functional relationship between the predicted response and the feature for individual instance.

Some explanations methods (including the ones presented here) are general in a sense that they can be used with any type of classification model (Lemaire et al. 2008; Robnik-Šikonja and Kononenko 2008; Štrumbelj et al., 2010). This enables their application with almost any prediction model and allows users to analyze and compare outputs of different analytical techniques. Lemaire et al., (2008) applied their method to a customer relationship management system in telecommunications industry. The method which successfully deals with high-dimensional text data is presented in (Martens and Provost, 2011). Its idea is based on general explanation methods presented here and offers explanation in the form of a set of words which would change the predicted class of a given document. Bosnić et al. (2014) adapt the general explanation methodology to data stream scenario and show the evolution of attribute contributions through time. This is used to explain the concept drift in their incremental model.

Many explanation methods are related to statistical sensitivity analysis and uncertainty analysis (Saltelli et al., 2000). In that methodology sensitivity of models is analysed with respect to models' input. A related approach, called inverse classification (Aggarwal et al. 2010) tries to determine the minimum required change to a data point in order to reclassify it as a member of a different class. A SVM model based approach is proposed by (Barbella et al., 2009).

Another sensitivity analysis-based approach explains contributions of individual features to a particular classification by observing (partial) derivatives of the classifiers prediction function at the point of interest (Baehrens et al. 2010). A limitation of this approach is that the classification function has to be first-order differentiable. For classifiers not satisfying this criterion (for example, decision trees) the original classifier is first fitted with a Parzen window-based classifier that mimics the original one and then the explanation method is applied to this fitted classifier. The method was shown to be practically useful with kernel based classification method to predict molecular features (Hansen et al., 2011).

MAIN FOCUS

General explanation methods can be applied to any classification model which makes them a useful tool both for interpreting models (and their predictions) and comparing different types of models. By modification of feature values of interest what-if analysis is also supported. Such methods cannot exploit any model-specific properties and are limited to perturbing the inputs of the model and observing changes in the model's output (Robnik-Šikonja and Kononenko 2008; Lemaire et al. 2008, Štrumbelj et al., 2010).

True causal relationships between the dependent and independent variables are typically hidden except in artificial domains where all the relations as well as the probability distributions are known in advance. Therefore only explanations of prediction process for a particular model is of practical importance. The prediction accuracy and the correctness of explanation for a given model may be orthogonal: the correctness of the explanation is independent of the correctness of the prediction. However, empirical observations show that better models (with higher prediction accuracy) enable better explanations (Štrumbelj et al., 2009). Two types of explanations are discussed:

- *Instance explanation* explains predictions with the given model of a single instance and provides impact of input feature values on the prediction.
- *Model explanation* aggregates instance explanations over many (training) instances, which provides top-level explanations of features and their values. This aggregation over many instances enables identification of different roles attributes may play in the classifications of instances. To avoid loss of information due to summarization, in the presented visualization the evidence for and against each class is collected separately. In this way one can, for example, see that a particular value of an attribute supports specific class but not in every context.

Two general explanation methods are presented which provide the two types of explanations for prediction models. The key idea is that the contribution of a particular input value (or set of values) can be captured by "hiding" the input value (set of values) and observing how the output of the model changes. As such, the key component of general explanation methods is the expected conditional prediction - the prediction where only a subset of the input variables is known. Let Q be a subset of the set S of all input variables $Q \subseteq S = \{X_1, \dots, X_n\}$. Let $p_Q(y_k|x)$ be the expected prediction for x , conditional to knowing only the input variables represented in Q : $p_Q(y_k|x) = E(p(y_k|x) | X_i = x_{(i)}, \forall X_i \in Q)$.

Therefore, $p_S(y_k|x) = p(y_k|x)$. In practical settings the classification function of the model is not known - one can only access its prediction for any vector of input values. Therefore, exact computation of this equation is not possible and sampling-based approximations are used.

EXPLAIN: One-Variable-at-a-Time Approach

The method EXPLAIN computes the influence of a feature value by observing its impact on the model's output. The EXPLAIN assumes that the larger the changes in the output, the more important role the feature value plays in the model. The shortcomings of this approach is that it takes into account only a single feature at time, therefore it cannot detect certain higher order dependencies (in particular disjunctions) and redundancies in the model.

The EXPLAIN assumes that the characterization of the i -th input variable's importance for the prediction of the instance x is the difference between the model's prediction for that instance and the model's prediction if the value of the i -th variable was not known, namely: $p(y_k|x) - p_{S-\{i\}}(y_k|x)$. If this difference is large then the i -th variable is important. If it is small then the variable is less important. The sign of the difference reveals whether the value contributes towards or

against class value y_k . This approach was extended in (Robnik-Šikonja and Kononenko, 2008) to use log-odds ratios (or weight of evidence) instead of the difference in predicted class probabilities.

To demonstrate behavior of the method an example of an explanation is given. Let a binary domain contains three important (A_1 , A_2 , and A_3) and one irrelevant attribute (A_4), so the set of attributes is $S = \{1, 2, 3, 4\}$. Let us assume that the learned model correctly expresses the class value as the parity (xor) relation of three attributes $C = A_1 \oplus A_2 \oplus A_3$. The correct model would classify an instance $x = (A_1 = 1, A_2 = 0, A_3 = 1, A_4 = 1)$ to class $C = 0$, and assigns it probability $p(C = 0|x) = 1$. When explaining classification for this particular instance $p(C = 0|x)$, method EXPLAIN simulates the lack of knowledge of a single attribute at a time, so one has to estimate $p_{S-\{1\}}(C = 0|x)$, $p_{S-\{2\}}(C = 0|x)$, $p_{S-\{3\}}(C = 0|x)$, and $p_{S-\{4\}}(C = 0|x)$. Without the knowledge about the values of each of the attributes A_1 , A_2 , and A_3 , the model cannot correctly determine the class value, so the correct estimates of class probabilities are $p_{S-\{1\}}(C = 0|x) = p_{S-\{2\}}(C = 0|x) = p_{S-\{3\}}(C = 0|x) = 0.5$. The differences of probabilities $p(y_k|x) - p_{S-\{i\}}(y_k|x)$ therefore equal 0.5 for each of the three important attributes, which indicate that these attributes have positive impact on classification to class 0 for the particular instance x . The irrelevant attribute A_4 does not influence the classification, so the classification probability remain unchanged $p_{S-\{4\}}(C = 0|x) = 1$. The difference of probabilities $p_S(C = 0|x) - p_{S-\{4\}}(C = 0|x) = 0$ so the explanation of the irrelevant attribute's impact is zero.

IME: All-Subsets Approach

The one-variable-at-a-time approach is simple and computationally less-intensive but has some disadvantages. The main disadvantage is that disjunctive concepts or redundancies between input variables will result in unintuitive contributions for variables (Štrumbelj et al., 2009). A solution was proposed in (Štrumbelj and Kononenko, 2010), where all subsets of values are observed.

Such procedure demands 2^a steps and results in the exponential time complexity. However, the contribution of the variable corresponds to the Shapley value for the coalitional game of a players. This allows an efficient approximation based on sampling.

SOLUTIONS AND RECOMMENDATIONS

The working and practical utility of the one-variable-at-a-time contributions and their visualization are illustrated on the well-known Titanic data set. The task is to classify the survival of a passenger in the disaster of the Titanic ship. The three input variables report the passengers' status during travel (first, second, third class, or crew), age (adult or child), and gender. Note the similarity of the problem with many business decision problems, such as churn prediction, mail response, insurance fraud, etc. As an example PRBF classifier is used which is a special case of RBF network. Such models usually provide good prediction accuracy but are incomprehensible. Left-hand side of Fig. 1 shows an example of an *instance explanation* for the prediction of instance x (a first class adult male passenger). The text at the top includes the data set name, the model name, the class value in question, the model's prediction for this class value, and the actual correct class value for the instance. The input variables' names are shown on the left-hand side and their values for the particular instance are on the right-hand side. The thick dark shaded bars indicate the contributions of the instance's values for each corresponding input variable towards (or against) the class value "survived=yes". The thinner and lighter bars above indicate average contributions of these values across all instances. For the given instance one can observe that "sex = male" speaks strongly against survival and "status=first class" speaks in favor of survival, while being an adult has little influence. Thinner average bars above them reveal that being male is on average less

dangerous and being in the first class is even more beneficial than in the selected case. Note that the same visualization can be used even if some other classification method is applied.

A more general view of the model is provided by averaging the explanations for the training data and their visualization in a summary form, which shows average importance of each input variable and its values. An example of such a *model explanation* for Titanic data set is presented in the right-hand side of Fig. 1. On the left-hand side the input variables and their values are shown. For each value the average negative and the average positive contributions across all instances is displayed. Note that negative and positive contributions would cancel each other out if summed together, so it is important to keep them separate. The lighter bars shown are equivalent to the lighter bars in the instance explanation on Fig. 1a. For each input variable the average positive and negative contribution across all values and instances is shown (darker bars). The visualization reveals that the crew status and gender have approximately the same effect while the age is less important in the PRBF model. Travelling in the first or second class has an exclusively positive contribution towards the survival, being a child or female has greater positive than negative contribution, travelling third class or being a male has a predominately negative contribution, while being a member of the crew or an adult has a minor negative contribution.

Real World Applications

To show a broad spectrum of possible practical applications of the described methodology, three applications from different fields are shortly described.

Breast Cancer Recurrence

In a real-life breast cancer recurrence prediction Štrumbelj et al., (2010) illustrate the usefulness of the visualizations and the advantage of using

the general explanation method. Several machine learning algorithms were evaluated. Predictions were enhanced with instance explanations using the IME method. Visual inspection and evaluation showed that oncologists found the explanations useful and agreed with the computed contributions of features. Examples of explanations provided by the non-transparent PRBF model, which achieves 73% classification accuracy, are presented in Figures 2. If oncologists chose to replace their existing prediction model with a better performing one, the form of visualizations would remain the same and would not affect the user-experience. This is an advantage of using a general explanation method.

Enterprise Performance

Pregeljc et al., (2012) used traditional modeling approaches together with data mining to gain insight into the connections between the quality of organization in enterprises and the enterprises' performance. The data set contained economic results and indicators of organizational quality for 72 Slovenian enterprises' in the time span of four years. The hypothesis that a causal relationship exists between the latter and the former was confirmed based on the analysis consisting of the use of several classification algorithms to study these relationships and the evaluation of the prediction accuracy of the companies' economic results. The best performing models were complex and difficult to interpret, especially for non-technical users. Therefore, the general explanation methods presented here were employed to explain the effect of individual features on the model's predictions. The results showed that data mining models are successful at modeling the dependency relationship. The explanation of the influence of the input features on the predicted economic results provided insights with a meaningful economic interpretation. The interesting economic relationships and successful predictions come mostly from complex models such as random forests and ANN. Without proper explanation and visualization, these models are often neglected in favor of

Figure 1. An instance explanation (on the left-hand side) and a model explanation (on the right hand side) for the PRBF model classifying the Titanic data set. The tiny bars in the instance explanation represent the average positive and average negative contributions of the values and are equal to the corresponding value-bars in the model explanation (note the difference in scale).

Figure 2. For the patient represented by the figure on the left-hand side the PRBF predicts a high likelihood of cancer recurrence (81%). While this prediction turned out to be incorrect as the cancer did not recur, the oncologist would have made the same prediction and agree that chance of recurrence is high due to lympho-vascular invasion (LVI = 1), while a low number of positive lymph nodes (nLymph = 0) and early stage of cancer (stage = 1) speak against recurrence. The patient on the right hand side is similar, but did not have lympho-vascular invasion. Therefore, the most relevant input variables speak against recurrence and the model correctly predicts a low chance of recurrence (6%).

weaker, but more transparent models. Experts from the economic-organizational field, which reviewed and interpreted the results of the study, agreed that such an explanation and visualization is useful and facilitates comparative analysis across different types of prediction models.

Forecasting Sales

Bohanec et al. (2015) constructed a real-world data set describing the sales history of a medium-sized company providing software solutions to clients in international B2B markets. The data set construction was motivated by possible improvements in understanding factors impacting the outcome of the sales process and improvements of the sales performance for new clients. Approximately 15 new (open) sales opportunities per month were analyzed with the help of an external consultant. Machine learning prediction models were used in knowledge discovery process to gain knowledge about the properties of decision process using general explanation methods EXPLAIN and IME. The analysis included explanations of individual decisions as well as the whole model. For new (open) cases decision makers were supported with the explanations to assess various scenarios with explanatory what-if analysis.

One can conclude that the explanation methodology presented is a useful tool for many different problems. It is especially important for problems where prediction performance has to be supplemented with model's transparency or knowledge discovery.

FUTURE RESEARCH DIRECTIONS

The explanation methodology presented has recently been implemented as R package ExplainPrediction (Robnik-Šikonja, 2015) making it freely available to data science community. The simplicity and elegance of the idea coupled with efficient implementation and visualization of instance and model based explanations will al-

low the application of the approach in new areas. Broader practical use shall spur additional research into explanation mechanisms and improvements in the visual design of explanations.

CONCLUSION

Two general methods for explanation of prediction models were presented. The methods allow explanation of individual decisions as well as the prediction model as a whole. Both of them can be efficiently computed and visualized. The explanations reveal how the individual input variables influence the outcome of otherwise completely opaque models, thus making it transparent and comprehensible. The general methods allow users to compare different types of models or replace an existing model without having to replace the explanation method. The explanation methods EXPLAIN and IME exhibit the following properties:

- **Instance Dependency:** Different instances are predicted differently, so the explanations will also be different.
- **Class Dependency:** Explanations for different classes are different, different attributes may have different influence on different classes (for two-class problems, the effect is complementary).
- **Model Dependency:** The decision process is taking place inside the model, so if the model is wrong for a given problem, explanation will reflect that and will be correct for the model, therefore wrong for the problem.
- **Capability to Detect Strong Conditional Dependencies:** If the model captures strong conditional dependency the explanations will also reflect that.
- EXPLAIN method is unable to detect and correctly evaluate the utility of attributes' values in instances where the *change in more than one attribute* value at once is needed to affect the predicted value. IME

method samples the space of feature interactions and therefore avoids this problem.

- **Visualization Ability:** The generated explanations can be graphically presented in terms of the positive/negative effect each attribute and its values have on the classification of the given instance.

KEY TERMS AND DEFINITIONS

Attribute Evaluation: A data mining procedure which estimates the utility of attributes for given task (usually prediction). Attribute evaluation is used in many data mining tasks, for example in feature subset selection, feature weighting, feature ranking, feature construction, decision and regression tree building, data discretization, visualization, and comprehension.

Domain Level Explanation: Tries to find the true causal relationship between the dependent and independent variables. Typically this level is

unreachable except for artificial domains where all the relations as well as the probability distributions are known in advance.

Expressive Power of Explanation: Describes the language of extracted knowledge: propositional logic (that is, if-then rules), nonconventional logic (for example, fuzzy logic), first-order logic, and finite state machines (deterministic, nondeterministic, stochastic).

Feature Contribution: A value assigned to a feature (or its value) that is proportional to the feature's share in the model's prediction for an instance.

Instance Level Explanation: Explanation of prediction of a single instance with a given model, that is, at the model level.

Marginal Effect of a Feature: A difference between model's prediction with the feature and without it, holding all other features intact.

Model Level Explanation: Aims is to make transparent the prediction process of a particular model. Empirical observations show that better models (with higher prediction accuracy) enable better explanation at the domain level.

Portability of Explanation: Describes how well the explanation technique covers the set of available models.

Quality of the Explanation: Can be judged by several criteria: accuracy (generalization ability), fidelity (how well the explanation reflects behavior of the model), consistency (similarity of behavior for different models trained on the same task), and comprehensibility (readability and size of the extracted knowledge).

The Concept of the Shapley Value and the Cost Allocation Between Cooperating Participants

D

Alexander Kolker
GE Healthcare, USA

INTRODUCTION

Game theory is a branch of applied mathematics that studies strategic situations in which participants (players) act in order to maximize their returns (payoffs). As such, game theory provides models of rational behavior (decision-making) for strategic interactions.

Many types of problems that involve decision strategies for cooperating or non-cooperating participants present a fruitful ground for the application of mathematical game theory (Dowd, 2004; Cachon & Netessine, 2004).

In particular, cost allocation problems arise in many situations in which participants work together, such as healthcare providers who have to coordinate patient care in order to reduce the cost and improve the quality of care. It is demonstrated that a natural framework for developing a methodology for cost allocation problems could be based on game theoretical concepts (Tijs and Driessen, 1986; Roth, 1988; Young, 1994; Moulin, 2003). Several concepts for determining the 'fair' cost allocation have been proposed but only a few of these concepts have been used in practice: the nucleolus and the Shapley value.

In this chapter, these two concepts are illustrated side by side. The focus is on examples of practical application of the Shapley value, specifically in healthcare settings. The following two cases are considered in details: (i) the general application of the Shapley value methodology for cost allocation between cooperating providers of care applied to the bundled payment model mandated recently by the Center for Medicare Services' (CMS), and (ii) an

important particular case, in which each participant uses only a portion of the largest participant's asset (the so-called airport game).

BACKGROUND

By pooling resources and cooperating the participants usually reduce the total joint costs and realize savings. The question arises is how the reduced costs or the realized savings should be fairly allocated between them.

There could be different definitions of fair allocation. Some of them are:

- **Equitable Allocation:** Gives everyone the same satisfaction level, i.e. the proportion each player receives by their own valuation is the same for all of them. This is a difficult aim as players might not be truthful if asked their valuation.
- **Proportional Allocation:** Guarantees that each player gets his share. For instance, if three people divide up an asset then each gets at least a third by their own valuation.
- **Envy-Free Allocation:** Everyone prefers his own share to the others. No one is jealous of anyone else. No one would trade his share with anyone else's.
- **An Efficient or Pareto Optimal Allocation:** Ensures that no other allocation would make someone better off without making someone else worse off. The term efficiency comes from the economics idea of the efficient market.

DOI: 10.4018/978-1-5225-2255-3.ch182

- **Merit-Based Allocation:** The more one brings to the coalition, the more one gets out of the division of the accumulated gains.

A concept of fairness is rather subjective. It depends on the participants' socio-economic views and other factors. The fairness schemes described in the next sections form a basis of the two most popular cost allocation approaches: the nucleolus (Tijs and Driessen, 1986; Saad, 2009) and the Shapley value (Roth, 1988; Young, 1994).

MAIN FOCUS

The Nucleolus Concept

The nucleolus can be defined as an equilibrium that finds the 'center of gravity' of the so-called core. The core is defined as a set of inequalities that meet the requirement that no participant or a group of participants pays more than their stand-alone cost. The fairness criteria used by the nucleolus is minimizing the maximum "unhappiness" of a coalition. "Unhappiness" (or "excess") of a coalition is defined as the difference between what the members of the coalition could get by themselves and what they actually get if they accept the allocations suggested by the nucleolus.

More formally, an n -player game is defined by the set $N = \{1, 2, \dots, n\}$ and a function $v(\cdot)$, which for any subset gives a number $v(S)$ called the value of S . The characteristic value of the coalition S , denoted by $v(S)$, is the payoff that all players in the coalition S could jointly obtain. Let x_i be a payoff for player $i = 1, 2, \dots, n$. The nucleolus solution is defined as $x = (x_1, x_2, \dots, x_n)$ such that the excess ("unhappiness") $e_S(x) = v(S) - \sum_{i \in S} x_i$ of any possible coalition S cannot be lowered without increasing any other greater excess. With this definition, the nucleolus is a solution that makes the largest "unhappiness" of the coalitions as small as possible.

There is no general closed-form formula for the nucleolus calculation, except for the recently

developed analytic solution for a particular three-player case (Leng and Parlar, 2010). In general, the nucleolus has to be computed numerically in an iterative manner by solving a series of linear programming (LP) problems, or by solving a very large-scale LP problem. More specifically, the linear programming problem formulation is (Saad et al, 2009):

$$Z \rightarrow \min$$

subject to:

$$Z \sum_{i \in S} x_i \geq v(S) \quad (1)$$

$$\sum_{i \in N} x_i = v(N) \quad (2)$$

The advantage of the nucleolus is that it always exists and that it is unique for all non-empty cores. Therefore, some researchers have used this concept to analyze business and management problems. As an early application of the nucleolus concept, Barton (1992) suggested the nucleolus solution as the mechanism to allocate joint costs among entities who share a common resource. At the same time, due to the complexity of the calculations for large coalitions, the nucleolus has not been extensively used to solve the various allocation-related problems.

Another problem with the nucleolus is that it does not exhibit the monotonicity property (Tijs and Driessen, 1986). Cost allocation concepts that do not exhibit monotonicity could result in having some members paying less if the total cost increases or having paid more if the total cost decreases. An example of a water supply project is available in which cost overrun would actually benefit some participants if the nucleolus method is used for allocating costs: the higher total project cost results in lowering contributions of some participants (Young et al, 1982). Thus, if regulatory agencies do not have the means of monitoring

actual demand and costs, the use of the nucleolus that does not exhibit monotonicity could result in an abusive practice by some participants.

The Shapley Value Concept

The focus of this chapter is the Shapley value because it exhibits some attractive properties (including monotonicity) and it is easier to compute than the nucleolus. Therefore, it is more widely used for practical applications (Young, 1994).

The Shapley value aims at the ‘fair’ allocation of collective costs or gained savings between the collaborating participants based on the relative (marginal) contribution of each participant to their cooperative activities. Basically, the more one brings to the coalition, the more one gets out of the division of the accumulated gains. This is an example of meritocracy fairness.

It should also be noted that an approach was developed in which player’s payoff depends on the worth of the coalitions to which one belongs and not necessarily on one’s marginal contributions, the so-called membership values (Kleinberg and Weiss, 2013). This means that one would get some share regardless of whether or not one makes a marginal contribution to the welfare of the coalition. It was demonstrated that the set of non-marginal membership values includes those that embody widely held notions of fairness, such as partial “benefit equalization”, individual rationality and “greater rewards follow from greater contributions”, where one’s contributions are not measured marginally.

Marginal Contribution

Each participant is supposed to bring some value to the group when he joins it. Participant’s added value or the marginal contribution is defined as surplus that is produced when this participant joins the group.

For example, four participants form a group (coalition). Without one member, the other 3 members produce each \$75 worth of a product.

If this member works alone then he can produce \$80 worth of the product. If he joins the group, then each group member will be able to produce \$85 worth of the product. The one’s added value to the group is defined as $\$85 \times 4 - \$75 \times 3 - \$80 \times 1 = \35 , i.e. $\$85 - \$80 = \$5$ for the newly joined member and \$10 for each of three others. This is also called the ‘marginal contribution’ of the participant. It is a measure of what this group member’s presence is worth, above the minimum that he would require for his service. Notice that if one cannot produce anything working alone (\$0) then the added value becomes greater, e.g. $\$85 \times 4 - \$75 \times 3 = \$115$, i.e. \$85 for the newly joined member and \$10 for each of three others. Thus, joining the group provides more benefit if one cannot produce anything alone.

The Shapley Value Definition

A group of k cooperating members is called coalition, s . All participating members form the grand coalition S that consists of all n participants, $k \leq n$. Each non-empty coalition has a value $V(s)$, which represents the cost (or the value of this coalition). The Shapley value provides a ‘fair’ allocation in the sense that all members are compensated proportionally to their merit, i.e. proportionally to their marginal contributions, $V(s) - V(s-k)$. These contributions are then averaged over all possible different combinations in which the coalition can be formed.

The Shapley value, Sh_k , for each participant k is calculated as

$$Sh_k = \sum_{S \subset n} \frac{(s-1)!(n-s)!}{n!} [V(s) - V(s-k)],$$

where s is the number of participants in coalition S ; summation is performed over all possible coalitions, which participant k joins; $(s-1)!$ is the number of arrangements for participants before joining s ; $(n-s)!$ is the number of arrangements for participants after joining s , and $n!$ is the total number of all possible coalition combinations.

Thus, the Shapley value is computed by calculating the average marginal contribution that participant k brings to a coalition (group) s if this participant joins any coalition, and all coalitions for this participant k are formed in random order (there is no way of taking advantage of a more favorable coalition order).

Participants have incentives to stay voluntarily in the coalition if three conditions are satisfied: (i) the participant's coalition cost is lower than its stand-alone cost (or the saving is higher). This condition is called individual rationality; (ii) any sub-groups' costs are lower than that of combined stand-alone costs of the sub-groups' participants (or the saving is higher). This condition is called sub-group rationality; and (iii) the total costs (savings) must be completely distributed among all cooperating participants, i.e. no participant's share of the costs can be reduced without increasing another participant's share. This condition is called total distribution rationality. If these conditions are satisfied, then the so-called core of cost sharing is not empty. Sometimes, though, the core can be empty. This means that there is no unique cost allocation that satisfies all participants' conditions. Hence, there is no incentive to voluntarily form the coalition and stay in it. The Shapley value can always be calculated even if the core is empty. If the core is not empty, then all participants have an incentive to voluntarily stay in the coalition and get their 'fair' cost (savings) allocation.

SOLUTIONS AND RECOMMENDATIONS

Example 1: Three-Member Group

For a long time, policymakers have been increasingly frustrated with fee-for-service payment system in healthcare settings. Fee-for-service rewards volumes and encourages silos and fragmentation of care. Several provisions of the Affordable Care Act (ACA) healthcare legislation in the United States

seek to shift provider payments to value-based approaches that encourage quality improvement and cost reduction. Payment bundling promoted by the Center of Medicare Services' (CMS) is one such approach. In this payment model a single (bundled) payment for the episode of care is paid to all providers of services through a contracting organization. The contracting organization is responsible for allocating the payments among all providers (hospitals, physicians, skilled nursing facilities, rehabilitation units, etc.). CMS offers no methodology for sharing the savings or the extra costs between providers. The providers themselves are supposed to use a methodology of their choice for 'fair' distributing the payments among them. The Shapley value methodology illustrated in this and in the following examples could serve as a good choice.

The benefits of increased alignment (cooperation) between healthcare providers have been well established. The bundled payment offers a number of opportunities for hospitals to accrue savings through reductions in actual hospital costs (operating expenses), decreases in length of stay (LOS), reduction or avoidance of readmissions, and management post-acute care (Pearce and Harris, 2010).

Suppose for simplicity that the contracting organization includes three main providers: hospital (H), physician group (PG), and skilled nursing facility (SNF).

Let's consider, as an example, the representative costs of care for some medical condition related to an acute care episode for individual providers presented, for example, by Pearce and Harris (2010, exhibit 1) and indicated on Figure 1, line 1. Let's further assume that the 2-member and the 3-member coalitions have achieved the percent (%) cost reduction vs. stand-alone members' costs presented in lines 3 and 6 on Figure 1, respectively.

The Shapley value costs for participants 1, 2 and 3 (the group size $n=3$) are calculated as:

Figure 1. Stand-alone costs and the Shapley costs allocation for group size $n=3$. All cores are non-empty.

#	Participant (member)->	Hospital {1}	Physician group {2}	SNF {3}	Total
1	Median Medicare cost for stand-alone providers per episode-of-care	\$30,000	\$6,000	\$4,000	\$40,000
2	2-members coalitions->	{12}	{13}	{23}	
3	Cost reduction for 2-members coalition vs. stand-alone member cost, %	3.0%	2.0%	1.5%	
4	Cost for 2-member coalitions	\$34,920	\$33,320	\$9,850	
5	3-member coalition->	{123}			
6	Cost reduction for 3-member coalition vs. stand-alone member cost, %	3.5%			
7	Cost for 3-member coalitions	\$38,600			
8	Shapley value for Hospital: provider {1}	Shapley value for Physician group: provider {2}	Shapley value for SNF: provider {3}	Total	
9	\$29,290	\$5,555	\$3,755	\$38,600	
10	Saving {1}	Saving {2}	Saving {3}		
11	\$710	\$445	\$245	\$1,400	
12	Saving allocation % {1}	Saving allocation % {2}	Saving allocation % {3}		
13	2.4%	7.4%	6.1%		
14	Coalition->	{12}	{13}	{23}	
15	Condition 1 for non-empty core: Shapley costs is less than stand-alone members' costs	OK	OK	OK	
16	Coalition->	{12}	{13}	{23}	
17	Condition 2 for non-empty core: two-member coalition costs are less than the combined members' costs	OK	OK	OK	

$$Sh_1 = w_1 * C_1 + w_2 * (C_{12} - C_2) + w_3 * (C_{13} - C_3) + w_4 * (C_{123} - C_{23})$$

$$Sh_2 = w_1 * C_2 + w_2 * (C_{12} - C_1) + w_3 * (C_{23} - C_3) + w_4 * (C_{123} - C_{13})$$

$$Sh_3 = w_1 * C_3 + w_2 * (C_{13} - C_1) + w_3 * (C_{23} - C_2) + w_4 * (C_{123} - C_{12})$$

where C_1 , C_2 , and C_3 are the costs for stand-alone providers, respectively; C_{12} , C_{13} , and C_{23} are

the costs for 2-member coalitions, respectively; and C_{123} is the cost for the 3-member coalition.

For $s=1$ the weight $w_1 = (1-1)!(3-1)!/3! = 1/3$; for $s=2$ the weight $w_2 = (2-1)!(3-2)!/3! = 1/6$; and for $s=3$ the weight $w_3 = (3-1)!*(3-3)!/3! = 1/3$.

These formulas were built in the Excel spreadsheet. Results are presented on Figure 1.

Lines 15 and 17 include checking conditions for voluntary staying in the coalition, i.e. the conditions that participant's coalition costs are lower than its stand-alone costs (or the savings is

The Concept of the Shapley Value and the Cost Allocation Between Cooperating Participants

higher)-individual rationality condition, and (ii) any sub-groups' costs are lower than that for the corresponding combined stand-alone costs of the sub-groups' participants (or the saving is higher)-sub-group rationality condition. 'OK' means that the corresponding condition is satisfied and that

the core is not empty. Thus, the participants have incentives to stay voluntarily in the coalition.

However, if the projected combined cost reduction (%) for three participants is a little bit lower, say, 3% rather than 3.5%, then the sub-group rationality condition for coalition {12} is violated. This is indicated on Figure 2, line 17, as 'Core is

Figure 2. Stand-alone costs and the Shapley costs allocation for group size $n=3$. Some cores are empty.

#	Participant (member)->	Hospital {1}	Physician group {2}	SNF {3}	Total
1	Median Medicare cost for stand-alone providers per episode-of-care	\$30,000	\$6,000	\$4,000	\$40,000
2	2-members coalitions->	{12}	{13}	{23}	
3	Cost reduction for 2-members coalition vs. stand-alone member cost, %	3.0%	2.0%	1.5%	
4	Cost for 2-member coalitions	\$34,920	\$33,320	\$9,850	
5	3-member coalition->	{123}

7	Cost for 3-member coalitions	\$38,800			
8	Shapley value for Hospital: provider {1}	Shapley value for Physician group: provider {2}	Shapley value for SNF: provider {3}	Total	
9	\$29,357	\$5,622	\$3,822	\$38,800	
10	Saving {1}	Saving {2}	Saving {3}		
11	\$643	\$378	\$178	\$1,200	
12	Saving allocation % {1}	Saving allocation % {2}	Saving allocation % {3}		
13	2.1%	6.3%	4.5%		
14	Coalition->	{12}	{13}	{23}	
15	Condition 1 for non-empty core: Shapley costs is less than stand-alone members' costs	OK	OK	OK	
16	Coalition->	{12}	{13}	{23}	
17	Condition 2 for non-empty core: two-member coalition costs are less than the combined members' costs	Core is Empty	OK	OK	

Empty'. Indeed, in this case, the Shapley value for provider 1 is \$29,357, and for provider 2 is \$5,622, respectively (compare to the values on Figure 1). Thus, their sum (\$34,979) exceeds the projected combined cost for stand-alone providers 1 and 2 (\$34,920). This makes the core empty. There is no financial incentive for providers 1 and 2 to stay voluntarily in the coalition. The coalition is likely to break down.

Using the developed spreadsheet, it is easy to play various input data scenarios to analyze which coalition is likely to voluntarily stay, and what would be the corresponding costs and savings allocations for the coalitions' members (providers).

Example 2: Four-Member Group

CMS comprehensive care for joint replacement (CJR) model went into effect on April 1, 2016 (Federal Register, 2015). Under this model, acute care hospitals in certain selected 67 metropolitan areas will receive retrospective bundled payments for episodes of care for lower extremity joint replacement. The providers are supposed to share the savings or bear the extra costs vs. the CMS baseline bundled cost.

According to Becker's Hospital Spine Review (Dyrda, 2016), the average Medicare cost breakdown per CJR episode includes 8 categories: inpatient hospital stay \$13,193; skilled nursing facility \$5,034; inpatient rehabilitation facility \$1,568; home health agency \$2,123; physicians \$1,675; hospital readmissions \$1,155; outpatient services \$604; and durable medical equipment \$122. To illustrate the Shapley cost allocation method let's combine for simplicity some of these costs to produce a 4-member participants group: inpatient hospital stay, physicians, hospital readmission (H), \$16,023; inpatient rehabilitation (IPR), \$1,568; skilled nursing facility (SNF), \$5,034; and home health agency, durable equipment, outpatient services (HHA), \$2,849. The total average baseline cost for the CJR episode of care is \$25,474.

As indicated on Figure 3, four providers can form 6 paired coalitions (line 2), 4 triple coalitions (line 5), and 1 grand coalition (line 8). Suppose that the 2-members' coalitions, the 3-members' coalitions, and the grand coalition have achieved the percent (%) cost reduction vs. stand-alone members' costs presented in lines 3, 6 and 9 on Figure 3, respectively.

The Shapley value for each provider contains 8 marginal values terms: 1 single, 3 double, 3 triple and 1 with grand coalition. These terms are summed up with coefficients $(1-1)!(4-1)!=6$, $(2-1)!(4-2)!=2$, $(3-1)!(4-3)!=2$, and $(4-1)!(4-4)!=6$, respectively, and the sum is then divided by $n!=4!=24$. These formulas were built in an Excel spreadsheet.

The Shapley values for all four providers, their savings and the percent of savings allocations are indicated on Figure 3, lines 11-16. The cores for all coalitions are not empty. All four providers have financial incentive to stay in coalitions because their stand-alone costs would be higher. The Shapley values allocate higher percentage savings to providers 2 (IPR) and 4 (HHA) (line 16) than simple cost-proportional allocations. This will likely encourage their cooperation with the hospital/physicians and SNF in providing coordinated patient care rather than position themselves as stand-alone providers.

At the same time, if the overall cost reduction for the contracting organization is only a little bit lower, say 4%, rather than 5%, then coalitions {13} and {134} will break-down, as indicated on Figure 4, lines 18 and 20. (To save space, only lines 8-20 of Figure 4 are included). Their corresponding cores are empty because the sum of the Shapley values for them will exceed the combined costs of the corresponding 2- and 3-member coalitions. Generally, the lower the percentage of cost reduction the higher the chances of breaking-down the voluntary coalition of providers. As in the previous example, it is easy to play various input data scenarios to analyze which coalition is likely to voluntarily stay, and what would be the corresponding costs and savings allocations for the coalitions' members (providers).

Figure 3. Stand-alone costs and the Shapley costs allocation for group size $n=4$. All cores are not empty.

#	Participant (member)->	Hospital (1)	IPR (2)	SNF (3)	HHA (4)		Total

20	Condition 3 for non-empty core: 3-member coalition costs are less than combined members' costs	OK	OK	OK	OK		

Simplified Shapley Value for Special Cases

The Shapley value formula is difficult to use when the coalition size increases above 4. The reason is that the number of permutations increases exponentially with the number of participants, and the costs data are needed for all k -member coalitions

($k=2, 3, 4, \dots, n$). These multiple cost data are difficult to get, or they are not known. Therefore, some special cases are important in which simplified or approximate expressions of the Shapley value are available (Reinhardt and Dada, 2005). In particular, there are widespread situations in which participants need to use only a portion of the available total capacity. The total capacity is

Figure 4. The Shapley costs allocation for group size $n=4$. Some cores are empty.

8	Grand coalition->	{1234}					
9	Cost reduction for grand coalition	4.0%

18	Condition 2 for non-empty core: 2-member coalition costs are less than the combined members' costs	OK	OK	OK	Core is Empty	OK	OK
19	Coalition ->	{123}	{124}	{134}	{234}		
20	Condition 3 for non-empty core: 3-member coalition costs are less than combined members' costs	OK	OK	Core is Empty	OK		

required to serve only the biggest participant. The users of the portions of the total capacity want to pay only their corresponding share of the biggest user's cost. One can think of toll roads, computer networks, or shared healthcare facilities.

One such practically important case is historically called an "airport game" developed originally for setting landing fees for different types of aircrafts (small and big) that share the same runway. The runway length (and the cost) is defined essentially by the biggest type aircraft that requires the full runway length while smaller type aircrafts can use only a portion of the total runway length. Littlechild and Owen (1973) first demonstrated that an empirical cost allocation rule for landing fees is the Shapley value in this particular case.

Let the cost of all stand-alone players be ordered from low to high, i.e.

$$C_1 < C_2 < C_3 < \dots < C_m,$$

where m is the number of types of players.

The number of players within each cost type are

$$n_1, n_2, n_3, \dots, n_m.$$

The total number of all players is $N = n_1 + n_2 + n_3 + \dots + n_m$.

Then, the Shapley value

for player 1 is $Sh_1 = C_1/N$

for player 2 is $Sh_2 = Sh_1 + (C_2 - C_1)/(N - n_1)$

for player 3 is $Sh_3 = Sh_2 + (C_3 - C_2)/(N - n_1 - n_2)$

for player 4 is $Sh_4 = Sh_3 + (C_4 - C_3)/(N - n_1 - n_2 - n_3)$

for player m is $Sh_m = Sh_{m-1} + (C_m - C_{m-1})/(N - \sum_{i=1}^{m-1} n_i)$

Table 1. Annual start-up and operating costs for new CDI

	Hospital 1	Hospital 2	Hospital 3	Hospital 4
Annual patient volumes	1000	950	800	1800
Estimated Annual Start-Up Costs	\$5M	\$4M	\$2M	\$9M

Thus, the pattern is that the Shapley value for each player is equal to that for the previous one plus the corresponding price differential divided by the total number of players but the sum of all previous smaller ones.

If only one player is present in each cost category, i.e. if $n_1=n_2=n_3=\dots=1$ then:

$$Sh_1 = C_1/N$$

$$Sh_2 = Sh_1 + (C_2 - C_1)/(N-1)$$

$$Sh_3 = Sh_2 + (C_3 - C_2)/(N-2)$$

$$Sh_4 = Sh_3 + (C_4 - C_3)/(N-3)$$

$$Sh_m = Sh_{m-1} + (C_m - C_{m-1})/(N-m+1)$$

These formulas can easily be built in an Excel spreadsheet to automate calculations.

Example 3

Four hospitals consider offering imaging service at a new Center for Diagnostic Imaging (CDI). Annual start-up and operating costs, as well as the projected number of patients that require service, are in Table 1.

The hospitals have agreed to use a portion of one largest \$9M facility that will serve their annual patient volumes.

How much will each hospital have to contribute to the largest facility?

What will be the minimal ‘fair’ charge per patient to recoup the costs over one year?

Step 1: Sort the costs in ascending order, i.e.

Hospital 3: $C_3 = \$2M$; 800 patients

Hospital 2: $C_2 = \$4M$; 950 patients

Hospital 1: $C_1 = \$5M$; 1000 patients

Hospital 4: $C_4 = \$9M$; 1800 patients

Step 2: Calculate the sum of all patient volumes:
 $N = 800 + 950 + 1000 + 1800 = 4550$.

Step 3: The Shapley value (minimal charge per patient):

Hospital 3:

$$Sh_3 = C_3/N = \$2M/4550 = \$439.56;$$

Total: $\$439.56 \times 800 = \$0.352M$

Hospital 2: $Sh_2 = Sh_3 + (C_2 - C_3)/(N - n_3) = \$439.56 + (\$4M - \$2M)/(4550 - 800) = \$972.89;$

Total: $\$972.89 \times 950 = \$0.924M$

Hospital 1: $Sh_1 = Sh_2 + (C_1 - C_2)/(N - n_3 - n_2) = \$972.89 + (\$5M - \$4M)/(4550 - 800 - 950) = \$1,330.04;$

Total: $\$1,330.04 \times 1000 = \$1.33M$

Hospital 4: $Sh_4 = Sh_1 + (C_4 - C_1)/(N - n_1 - n_2 - n_3) = \$1,330.04 + (\$9M - \$5M)/(4550 - 800 - 950 - 1000) = \$3,552.26;$

Total: $\$3,552.26 \times 1800 = \$6.394M$

Total cost is $\$0.352M + \$0.924M + \$1.33M + \$6.394M = \$9M$, i.e. the cost of the largest facility.

Example 4

Four dental groups consider opening dental clinics. The number of dentists and the total start-up costs are given in Table 2 (SNDP Manual, 2011).

If the dental groups use the corresponding portions of one largest 12-chairs clinic what will

Table 2. Dental clinic comparison chart: Capacity and costs for fixed clinics, and clinics using portable equipment

Size	3 Chairs	6 Chairs	9 Chairs	12 Chairs
Number of dentists	1	2	3	4
Total estimated Start-Up Costs	\$624,452	\$1,016,217	\$1,268,330	\$1,549,538

be the cost allocation for each dentist and the dental groups?

Total number of all dentists is $N=10$.

$$Sh_1 = \$624,452/10 = \$62,445 \text{ for dentist } 1.$$

$$Sh_2 = \$62,445 + (\$1,016,217 - \$624,452)/(10-1) = \$105,974 \text{ for dentist } 2.$$

$$\text{Total for dental group 2: } \$105,974 * 2 = \$211,948.$$

$$Sh_3 = \$105,974 + (\$1,268,330 - \$1,016,217)/(10-1-2) = \$141,990 \text{ for dentist } 3.$$

$$\text{Total for dental group 3: } \$141,990 * 3 = \$425,970$$

$$Sh_4 = \$141,990 + (\$1,549,538 - \$1,268,330)/(10-1-2-3) = \$212,292 \text{ for dentist } 4.$$

$$\text{Total for dental group 4: } \$212,292 * 4 = \$849,168.$$

Total cost for all dental groups is \$1,549,538, i.e. the cost of the largest facility.

Let's now consider only four dentists' groups without taking into account the number of dentists within each group. This means that we have only 1 member in each cost category; thus, $N=4$. In this case the Shapley values for each dental group are:

$$Sh_1 = C_1/N = \$624,452/4 = \$156,113$$

$$Sh_2 = Sh_1 + (C_2 - C_1)/(N-1) = \$156,113 + (\$1,016,217 - \$624,452)/(4-1) = \$286,701$$

$$Sh_3 = Sh_2 + (C_3 - C_2)/(N-2) = \$286,701 + (\$1,268,330 - \$1,016,217)/(4-2) = \$412,757$$

$$Sh_4 = Sh_3 + (C_4 - C_3)/(N-3) = \$412,757 + (\$1,549,538 - \$1,268,330)/(4-3) = \$693,965$$

Total for 4 dental groups is \$1,549,538, i.e. the cost of the largest facility.

FUTURE RESEARCH DIRECTIONS

As it was previously mentioned, the Shapley value formula is difficult to use when the group size n is greater than 4 because the number of double, triple, etc. permutations, P , increases exponentially with the group size as, $P = 2^n - (n+1)$. For example, for a modest group size $n=10$, more than 1000 sub-groups and their marginal costs should be considered. This is impractical. Although some special approximations were developed, such as an airport game, more research is needed for further developing other Shapley value approximations for large group sizes. Specifically, an approximation should be developed that does not necessarily require evaluating every possible coalition using, for example, the constraint generation technique.

Another research direction is further developing the concept of coalitional value, i.e. the possibility that some players may be more likely to act together than others. Despite the fact that coalition structures arise naturally in cost allocation problems, their applications have not been explored sufficiently (Costa and Garcia_Jurado, 2013). Taking into account the excellent properties of the Shapley value, it is natural to study how the Shapley values perform for games with a coalitional structure.

CONCLUSION

Cost allocation problem often arises in many business situations that benefit from the effect of cooperating partners. Examples are bundled payment to healthcare providers; pooling resources where savings from cooperation must be distributed ‘fairly’ between the participants, such as distribution of surgical costs in the presence of patient queues (Gonzalez and Herrero, 2004); joint hospitals’ imaging or surgical centers, etc.

A natural framework to study cost allocation problems is based on game theory approach. About a dozens of alternate concepts have been proposed to determine the ‘fair’ costs or savings allocation but only a few of them have been used in practice: the nucleolus and the Shapley value. It should be realized that there is no one best ‘fair’ cost allocation method. The choice of a method depends on the participants’ ideas about ‘fairness’, their economic and political views, and other subjective factors. Also, the ease of calculation and interpretation plays a significant role for the practical use.

The Shapley value’s axiomatic basis has some shortcomings (Tijs & Driessen, 1986; Young, 1994). Nonetheless, the attractive features of this concept make it valuable for various applications, especially in healthcare settings where providers’ cooperation and team based care is currently a long-term strategy for improving quality of care and cost reduction.

KEY TERMS AND DEFINITIONS

Bundled Payment: A payment model to healthcare providers in which one single payment is disbursed to cover an episode of patient care through a contracting organization. The contracting organization is responsible for allocating the payments among all providers.

Coalition: A group of k cooperating partners.

Cost Allocation: A problem that arises in many business situations that benefit from the effect of economy of scale or cooperating partners.

Core: A set of inequalities that meet the requirement that no participant or a group of participants pays more than their stand-alone cost.

Empty Core: A lack of unique cost allocation that satisfies all participants. If the core is empty, then unsatisfied participants have incentive to leave the cost sharing coalition.

Game Theory: A branch of applied mathematics that studies strategic situations in which participants (players) act rationally in order to maximize their returns (payoffs).

Marginal Contribution: A value of the group with the player as a member minus the value of the group without the player minus the value created by the player working alone.

Nucleolus: A game theory concept defined as minimizing the maximum “unhappiness” of a coalition. “Unhappiness” (or “excess”) of a coalition is defined as the difference between what the members of the coalition could get by themselves and what they are actually getting if they accept the allocations suggested by the nucleolus.

Shapley Value: A game theory concept aimed at the ‘fair’ allocation of the collective costs or profits (savings) between several collaborative participants. It is based on allocating the costs to the cooperating participants proportionally to the marginal contributions of each participant that is averaged over all possible combinations in which participants can cooperate.

Decision Filed Theory

INTRODUCTION

Development advanced ICT based systems, applications and services for improving our daily life require understanding and modeling of how people make decisions. The human decision making has been of interest, and theories been developed, in different fields of science, including economics, psychology, sociology and computer science. There exist a number of well-known and widely applied decision making theories, such as causal decision theory, evidential decision theory and game theory. In ICT field, formal decision making models are used, for example, in developing decision support systems, artificial intelligence solutions and intelligent services. Growing number of application of these systems can be found in such areas as electronic commerce, intelligent traffic and health.

Decision Filed Theory (DFT) is one of the younger human decision making theories that has significant potential for practical applications in real-world decision making situations. It employs a dynamic decision making model, compared to static models that most of the traditional decision theories are relying on, and builds on psychology, whereas the earlier models are commonly based on economics and rational utility theories. These characteristics make it potentially useful for present day application needs. Along with development of technology, the DFT has been studied for solving various kinds of decision making problems in different contexts. Several

successful empirical studies have shown that DFT theory is able to explain human's dynamic behavior in many areas and it can be applied as a basis for ICT system design.

By a glance to the existing research, we can see that the DFT has been adapted to different application contexts. However, for having stronger evidence for its validity to practical empirical cases and understanding its trends and current state, the existing scientific literature needs to be reviewed and analyzed more systematically and in a structured way. This article presents the results of our study, where we analyze and synthesized the existing research knowledge on DFT with the means of Systematic Literature Review (SLR). The purpose is to give an evidence based view to the development of Decision Field Theory and its applications, which offers an understanding of its validity for practical applications and future potential.

BACKGROUND

Decision Field Theory, initially proposed by Busemeyer and Townsend (1993), is a dynamic cognitive approach to describe and explain human decision making under risk and uncertainty. It provides a formal theory and a mathematical model of human decision behavior, which takes into account two of the basic phenomena of human decision making that are not covered by most of the other theories: variability of preference of choices

and systematic relation between preferences and deliberation time (Busemeyer & Townsend, 1993). Before the theory has been applied to solve multiple options problems of decision making, it has experienced several stages that are the foundation for present theory. The early deterministic subject expected utility (SEU) theory is restricted to the choices between two options (Savage, 1954). This theory can be applied to predict the trend of preferences on options, but it can't explain the dynamic change of preference. It was followed by the Sequential SEU Theory (DeGroot, 1970), which take into account the sequential order of consecutive decisions. The main problem of the Sequential SEU theory is that the knowledge and experience in the past has no influence on current decision making, which goes against with real human deliberative process. The Random Walk SEU Theory (Busemeyer, 1985) solves this problem by setting an initial preference state. The deterministic decision making theories originate from the basic proposal that the action is either true or false between two conflict actions, which is referred to binary preference relation (Fishburn, 1988). In subsequent, it was used for two or more attributes decision making under dynamic environment (Diederich, 1997). After that, DFT was gradually mature and widely used.

DFT is a method that provides insights into relationship between preference evolution and dynamic decision making. The following original and classic mathematical equation is used to explain the dynamic evolution of preferences during the deliberation time.

$$P(t+h) = SP(t) + V(t+h)$$

In this equation, P is the Preference vector, S is the Growth-decay matrix and V the Valence vector, which are explained below. The equation can be decomposed further as

$$p_i(t+h) = s_{ii} \cdot p_i(t) + \sum_{k \neq i} s_{ik} \cdot p_k(t) + v_i(t+h)$$

In general, DFT consider time as a dynamic factor which lead to frequent change in human's preference among various options. So for the time series $\{t_0, t_1, t_2, \dots, t_j, \dots, t_n\}$, the preferences on options fluctuate upon specific time point and forms preferences series $\{p_0, p_1, p_2, \dots, p_j, \dots, p_n\}$. In the equation, the time points t and $t+h$ are two adjacent time moments, and parameter h , referred as time unit, denotes the distance between two moments of decision making. From microscopic side, decision making is a continuous process when the moment is sequential. So, the length of h approaches to zero in the limit (Abad, 2014). While from the macroscopic side, decision making is intervallic. Thus, time unit h is equal to an arbitrary value.

Preference Vector P

The row vector $P(t)' = [P_1(t), P_2(t), \dots, P_n(t)]$ represents the preference state at time t for the n options.

Growth-Decay Matrix S

The decision makers' perception of decision case is not only determined by current information, but it also would be affect by their previous knowledge or similar experience (Van Horne, 1967). Consequently, the preferences value in current moment is influenced positively or negatively by the decision makers' memory. The matrix S , referred as feedback vector, is formed as $S = (I - h\Gamma)$ that is assumed to be symmetric ($r_{ij} = r_{ji}$ for all i, j). The diagonal elements of s_{ii} provide memory for previous states of the system. The off-diagonal values of s_{ik} allow for competitive interactions among competing alternatives. The researchers (Busemeyer et al., 2008; Qin et al., 2013) explain the implication of s_{ii} value in four following conditions.

- $0 < s_{ii} < 1$ indicates that memory of decision maker has positive feedback on current decision problem.

Figure 1. Mechanism of DFT elements
(adapted from Qin et al. (2013))

- $s_{ii} > 1$ suggests that memory of decision maker has negative feedback on current decision problem.
- $s_{ii} = 0$ means that memory of decision maker has no influence on current decision problem.
- $s_{ii} = 1$ expresses that memory of decision maker has perfect impact, not decay or growth, on current problem.

Valence Vector V

The row vector $V(t)' = [v_1(t), v_2(t), \dots, v_n(t)]$ represents the valence input at time t for the n options. The valence vector $V(t)$ is consists of three matrices.

$$V(t) = CMW(t)$$

At time t , the anticipated value of an option on an attribute is compared with the anticipated values of other options on the same attribute. These comparisons produce a valence for each option, denoted $v_i(t)$, for the valence of option i at time t . The matrix C is called contrast matrix, the elements of which are valued as $c_{ii} = 1$ and $c_{ij} = -1/(n-1)$ for $i \neq j$ where n is the number of option. Matrix C is defined to compare all the options between each other and the structure of it guarantees the sum of $V(t)$ components always equals to 0. M is called attribute matrix that is an $n \times m$ matrix (n is the number of options and m is the number of attribute). The attribute matrix M

represents decision makers' evaluations for each option on each attribute under certain conditions. $W(t)$, called weight matrix, is a $m \times 1$ matrix (m is the number of attribute) that indicates the weights of attention people allocates to each attribute of M . Simply put, the number of each weight value indicates how important the attribute is in decision. The decision of people is changing moment by moment, which is caused by the variability of $W(t)$.

The Figure 1 illustrates the mechanism how each of the element of the model act in DFT. From this model you can see the deliberation process of people and the reasons causing dynamic decision making.

The essence of dynamic decision making is the changes on preferences value on options. The evolution process of preference state is the result of dynamic valence that is consists of three elements: contrast matrix C , attribute matrix M and weight matrix W . In original DFT model, the value of contrast matrix and attribute matrix is constant while the value of weight matrix is changeable.

DFT RESEARCH TRENDS AND APPLICATIONS

DFT was introduced in 1993 as a response to the limitations of static deterministic models of human decision making. Since then it has been utilized in many application domains and also validated with many different cases. In the field of supply chain management, a method of dynamic decision

making is structured in order to realize strategic vendor selection or switching based on the principle of hierarchical planning (Sucky, 2007). The results showed that the proposed method is able to explain behavior of vendor selection, and then decision maker could choose the optimal solution of vendor management among alternative offers. In the stock market, DFT is used to analyze and avoid risks based on the experiences (Cohen et al., 2008). In this study, the authors set up a model representing preferences under uncertain environment where the current risks are dependent on experience. Vescoukis et al. (2011) have proposed an architecture based on dynamic decision making in disaster management for plan constructing, retrieving, and exchanging. This architecture not only predicts human decision making in disaster management, but also provides recommendation and evaluation for solution of disaster management. Moreover, DFT is also adopted in many other contexts, such as transportation, agriculture and military (Cheung et al., 1999; Pearson et al., 2010; Du et al., 2010).

In general, the research, development and the extent of the DFT applications in time and with respect of various application domains is not well known. Aggregated knowledge of its successful validation in various empirical cases is not available. In order to address this gap of knowledge, to we have carried out a Systematic Literature Review (SLR) for synthesize the existing knowledge. Our literature review questions were the following.

RQ1: What has been the focus and trends in DFT related research?

RQ2: What are the practical application contexts where DFT has been applied?

By aggregating evidence of DFT and its practical application from large amount of studies, the development, current situation and future directions of DFT research can be assessed.

Systematic Literature Review Process

The SLR conducted in this study was done following the principles of the guidelines proposed by Kitchenham (2004). The phases of the process are described below.

Literature Databases

In this literature review, the following four literature databases were used. These literature databases can be expected to cover comprehensively the scientific publications on the topic.

- **Scopus:** Covers over 21.000 peer-reviewed titles from more than 5,000 international publishers and over 5.5 million conference papers.
- **ScienceDirect:** Includes publications for scientific, technical and medical research.
- **IEEE Xplore:** Includes 121 IEEE transactions, journals, magazines and over 400 conference proceedings published since 1988 plus select content back to 1950, and all current 900 IEEE standards.
- **ACM:** Includes all computer science literature originating to Association for Computer Machinery.

Search String

As the focuses of the study was to review the applications of DFT, the major search terms were chosen to be “Decision Field Theory” and “Application”. The synonyms, abbreviations and alternative spellings were identified. After several trials searches with different combination of terms, final search string was specified as:

(decision field theory OR dynamic decision making)
AND
(application OR model OR system OR framework OR software)

Selection Criteria

Based on the characteristics of review questions, the inclusion and exclusion criteria were pre-defined as follows.

Inclusion criteria (IC):

- IC1:** The paper should be conference paper, or journal paper, or book chapter, or survey report and written in English; the paper should be related to the topics specified by the search string.
- IC2:** The articles propose context in which the decision field theory or dynamic decision making approach is applied. Meanwhile, corresponding application or model (or system or framework or software) is developed.
- IC3:** The paper detail the generation process of application or model (or system or framework or software).

Exclusion criteria (EC):

- EC1:** The duplicated articles caused by combining of the different literature databases should be removed; the papers irrelevant to the topics specified by the search string should be rejected.
- EC2:** The context addressed is related to automatic decision making, for example, robotic studying, military command management, multi-core chip research and so forth.
- EC3:** The article only introduces basic and general conception or history of decision making.

Screening Process

Then, paper selection and screening was conducted rigorously in three steps, complying with the specified inclusion and exclusion criteria. The searching of the databases identified altogether 790 papers, which were screened according the following steps.

In the Step 1, the duplicates of the papers were removed and the inclusion and exclusion criteria

IC1 and EC1 were applied. During the process of Step 1, the title, keywords and abstract was also read, and the papers not related to the topic were rejected. Additionally, the papers were labeled according the application types by the keywords: Automatic (short for “automatic decision making”), Support (short for “decision support for human decision making”), Other (related to subject indirectly or the application type could not be identified exactly). After reading keywords, abstract and title, the papers labeled in support, automatic and others were accept while the irrelevant papers were reject. Consequently, the accepted papers were passed to Step 2 for further selection and the rejected papers were excluded.

In the Step 2, the inclusion and exclusion criteria IC2 and EC2 were applied to the papers remaining of the previous step. In this step, the papers were further classified according the research type to Application (short for “application of DFT”), Theory (short for “theory of DFT”) and Other (related to subject indirectly or the research type could not be identified exactly). The irrelevant papers were rejected. The accepted papers were then passed to the following step for further screening. As the focus of the study was DFT application to decision support, the Step 3 was carried out only to the papers belonging in the classes of application type Support and research type Application. The papers with a focus on automatic decision making or theory were excluded from the next step.

In the step 3, the IC3 and EC3 criteria were used for reviewing the remaining papers that belonged to the classes of application type Support and research type Application. The requirements in this step were that the paper should clearly present the application of the DFT in detail, rather than having only a general description, and paper must have a clear application context in which the DFT is applied. This final screening step resulted in 62 primary papers that were further used for full detailed review and analysis. The flow diagram of the whole process is presented in the Figure 2 below.

Figure 2. Study selection process

The number of the papers after each step is presented in Table 1 by the literature databases. From the table you can see that initially the Scopus contributes the largest amount of papers on the topic, followed by ACM. ScienceDirect and IEEE included the least relevant papers. However, considering the primary papers after the last step, where the applications of the DFT in decision support is in focus, ScienceDirect contains highest percentage of relevant papers, followed by IEEE.

DFT Research Focus and Trends

During the paper screening process Step 1 and Step 2, the papers were classified according the application type {*Support*, *Automatic*, *Other*} and research type {*Application*, *Theory*, *Other*}. The class *Other* in both of the types indicates that the paper could not be clearly classified to neither of the other classes in the review process. The classification of the DFT related papers ac-

Table 1. Number of papers by the databases after each step

Step	Scopus	IEEE	ACM	ScienceDirect	Total	Percentage Remaining After the Step
Database Search	477	89	133	91	790	100%
Step 1	308	86	130	90	614	78%
Step 2	251	83	81	84	499	63%
Step 3	22	11	10	19	62	8%
Primary Paper Percentage	5%	12%	8%	21%	8%	

Table 2. Frequency of different types of papers

Classification	Support	Automatic	Others	Total
Application	62	73	0	135
Theory	208	12	134	354
Others	0	10	0	10
Total	270	95	134	499

cording their types allows us to map and analyze the popularity and trends of the DFT research. The focus of the DFT research can be analyzed by cross-tabulating the two paper types to form publication frequency Table 2.

From the Table 2 we can see that the number of published theory papers (354) is about two and a half times the number of application papers (135).

On the other hand, the relationship of the decision support papers frequency to the decision automation papers frequency is at the similar level. Based on that, we can conclude that DFT research has focused, until now, mostly on DFT theory (354) and on decision support (270). The theory of DFT in decision support appears to be clearly the most frequent research topic (208 papers).

Figure 3. Frequency of published DFT papers by application type

Figure 4. Frequency of published DFT papers by research type

The next interesting question is the trend of research interest in dynamic decision making and DFT during the time. The Figure 3 shows the frequency of the published papers till year 2014 by application type and Figure 4 by research type.

The figure shows clearly how the interest in DFT has been continually increasing during the years. The growth is seems to be almost exponential. Interest in decision support appears to be growing more than in decision automation. This can be caused by the growing interest in decision support systems and decision methods in ICT research during the last years, and also that DFT maybe suits better for supporting human decision making than for decision automation.

The Figure 4 shows that the number of publications on both Application and Theory have been

increasing, relatively approximately at the same phase. This result could imply that while the DFT applications are of growing interest, the theory is still at some level also in developing phase and there are possibilities to improve it.

DFT Application Areas

The analysis of the publication frequencies and trends of research papers clearly showed the increasing interest in developing and applying dynamic decision making and DFT. Growing number of research papers are reporting successful application of DFT to different empirical situations and cases. In order to gain understanding of the extent of these applications, we reviewed and analyzed the 62 decision support application

papers that were identified as the primary studies in our SLR screening Step 3.

The DFT appears to have been widely applied into many areas. For the purpose of the analysis, we categorized the application areas appearing in the primary studies according their context into 8 categories: (1) Energy use management; (2) Decision making behavior and process of Human; (3) Manufacturing and retail industry; (4) Transportation tool allocation or routing; (5) Disaster management; (6) IT technology; (7) Social, Economic and Medical issues; (8) Others. The results of the review and analysis are presented in the Table 3.

Seeing from the context categories of all primary studies, DFT theory is widely used in all sector of society. Broadly speaking, most researchers focus on social, economic and medical industries that account for 10 out of 62 papers. The energy management industry and human decision making behavior are right behind, with 9 relevant papers respectively, followed by manufacturing and retail industry. The difference in numbers of studies across different domains is very small.

The distribution of the application over so wide variety of application areas show that the DFT is not limiting in its application possibilities and that it is gaining more popularity across the different fields of applied sciences.

It was also observed that the primary studies include practical applications of many different DFT types and variations, for example rule-based decision field theory, multi-criteria decision field theory, multi-alternative decision field theory, and time critical decision field theory. The researchers (Roe et al., 2001) rebuild decision field theory as a connectionist network and use it to encompass multi-alternative decision making that is adopted successfully in economic or psychological context (Usher, 2004). The rule-based decision field theory is firstly generated by Johnson et al. (2005) and subsequently apply in routing field to study driver behavior (Gao, 2011) or control driving speed (Zhao, 2011). Lin et al. (2008) propose a dynamic multi-attribute decision making model to deal with the problem of uncertain information and aggregate the multi-period evaluations.

Table 3. Context categories of the DFT decision support application studies

Category	Context	Amount	Percentage
Social, Economic and Medical issues	Trading (2); Stock market; Business risk management; Social security(3); Patient management; Medicine (2)	10	16%
Energy use management	Electricity market (3); Power market; Mineral resource; Water management (2); Petroleum industry; Material recycle	9	15%
Human decision making behavior and process	Market participant behavior (3); Pedestrian behavior; Human behavior (3); Human decision making process(2)	9	15%
Manufacturing and retail industry	Supply chain; Supplier and retailer; Supplier selection (3); Vendor selection; Garment style design; Strategic planning forecast	8	13%
Transportation tool allocation or routing	Vehicle allocation; Port berth allocation; Container dispatching; Routing(4)	7	11%
IT technology	Air combat tactics; Ubiquitous; Game playing; Spam mail mitigation; Future call predication; Multi-sensor detection	6	10%
Disaster management	Disaster management	5	8%
Others		8	13%

FUTURE RESEARCH DIRECTIONS

Our systematic literature review of past DFT related research confirmed that the researchers and practitioners have a growing interest in developing and extending the DFT theory and model further as well as apply it in more widely in new contexts. This reveals the two main research directions, theoretical and practical: extension and validation of the DFT model to be applicable to more complex and realistic decision making situations and extending the practical applications of the DFT to new areas.

In our systematic literature review, we have identified the published papers studying the DFT theory and its applications, and reviewed more deeply the decision support application papers. This approach appeared to be successful for gaining evidence on the trends and current situation of the DFT research. Therefore this type of research would be recommendable to be taken further with more extensive and deeper analysis. For example, the DFT application cases could be analyzed and evaluated for gaining better understanding how well and trustworthily the applicability and efficiency of the DFT has been validated.

CONCLUSION

ICT technology is allowing development of increasingly advanced applications and services for supporting and automating our daily living and related small and big decisions. Therefore human decision making, related theories and models, are gaining more attention. Both researchers and practitioners are interested in finding applicable formal models for modeling, explaining and predicting human decision making that can be used for designing new applications and services. The DFT, as a dynamic decision model, which has more grounding on psychological than economic principles, is able to model natural human decision making processes well in many situations. Its dynamic decision model is in many cases better

than the theories that are relying on static decision models. Our review study revealed that DFT has also practically validated in many reported empirical cases that present wide variety of application contexts. The study also showed that the interest in the DFT has been growing almost exponentially during the last years. The research on both theory and applications are actively going on and expanding. As a rather young theory, DFT has still need for extensions; that was also shown in the trends that our systematic literature review revealed. In its current forms, it is still limited to relatively simple decision making cases that are not covering completely the complexity of real world practical situations and the bounded rationality (cf. Simon, 1955) of human decision making. However, it has a high potential to be further developed and adapted to new kinds of application contexts.

KEY TERMS AND DEFINITIONS

Decision Field Theory (DFT): A dynamic-cognitive theory and model of human decision making.

Dynamic Decision Making: Decision making under uncertainty in a changing environment where the consequences of the earlier decisions and actions affect to the present decisions.

Effectively Communicating With Group Decision Support Systems Using Information Theory

D**Jamie S. Switzer***Colorado State University, USA***Ralph V. Switzer***Colorado State University, USA*

INTRODUCTION

This entry describes the results from a case study conducted using information theory to examine the effectiveness of communicating using group decision support system (GDSS) technology. At its most basic level, information theory provides the means to measure the efficiency of communication systems. Using information theory as the theoretical foundation, this entry examines how the use of GDSS facilitated computer-mediated communication (CMC) for one particular business with respect to entropy, redundancy, and noise, which are key components in information theory.

BACKGROUND

As originally articulated, information theory is actually a mathematical theory grounded in the field of electrical engineering designed to evaluate the performance of communication systems (Mahowald, Fedorenko, Piantadosi, & Gibson, 2013; Ziemer & Tranter, 2002). Claude Shannon was an electrical engineer and mathematician working at Bell Laboratories in the 1940's. In 1948 he published his landmark paper, "A Mathematical Theory of Communication" (Shannon, 1948). This seminal work was concerned with the transmission and storage of information (Lafrance, 1990), and provided "the analytical

tools to evaluate the amount of information contained in message signals, and to compare the performance of actual systems" (Carne, 1999, p. 172). According to Gallager (2001), Shannon's theory established a conceptual basis for modern digital communications, particularly with regard to data compression, data encryption, and data correction (Gappmair, 1999).

Information theory has been applied to many disparate disciplines, such as computer science, statistics, cybernetics, physiology, psychology, library science, biology, physics, economics, music, and art (Asadi, 2015; Dahling, 1962; De-Fleur & Larsen, 1987; Overstreet, 1984; Pierce, 1980). In the field of communication, information theory has been applied to such areas as speech, linguistics, forensics, broadcasting, journalism, and even animal communication as studied by animal scientists (McCowan, Doyle, & Hanser, 2002; Scott-Phillips, 2015; Stephens, Barrett, & Mahometa, 2013; Watt & Krull, 1974).

There is some disagreement among scholars as to the applicability of information theory to the field of communication, in the non-technical, non-engineering sense (Cherry, 1957; Devlin, 1999; Weaver & Weaver, 1965; Young, 1987). Shannon himself initially cautioned against applying his theory to human communication (Haken & Portugali, 2015, p. 33; Rogers & Valente, 1993). But Shannon, in conjunction with Warren Weaver, did express some "optimism as to its wider ap-

plicability” (Warner, 2001, p. 24). In subsequent years other communication scholars have also explored more general applications of information theory (Pierce, 1980; Rogers & Valente, 1993). Indeed, Shannon’s simple yet elegant model of communication systems forms the basis of many introductory communication courses.

At its most basic level, information theory provides the means to measure the efficiency of communication systems. An information source sends a message (of any type) using a transmitter that carries a signal through a channel. The receiver then receives that signal, and the message arrives at its destination. There are additional factors, however, impacting the effective operation of that process, including entropy, redundancy, and noise.

Entropy, as defined by information theory, is concerned with the many different ways a message can be constructed, depending on the circumstance. An ambiguous or vague message, for example, has a high degree of entropy because the receiver cannot accurately interpret the message that the sender intended, and there is a measure of uncertainty and unpredictability regarding the message (Heath & Bryant, 2000). A message that is clear and concise will reduce the amount of entropy in a given situation.

Redundancy also reduces entropy. The more the same information is conveyed in a particular message, the more certain the receiver is of the interpretation of the message as the sender originally intended. There must be a balance of entropy and redundancy in an effective communication, but that balance is often impacted by the amount of noise present in the channel used to convey the message (Severin & Tankard, 2001).

Noise is simply some sort of interference that occurs in the transmission of the message between sender and receiver (Perry, 2002). Noise can take many forms, including extraneous information that causes a loss of intended information. The noisier the channel, the greater the need for redundancy (Cragan & Shields, 1998; Stephens et al., 2013). Anything that comes along with the signal that was not put there by the information source is noise.

Group Decision Support Systems (GDSS) are computer-based systems “designed to help committees, project teams, and other small groups with activities such as problem identification and analysis, decision making, planning, creativity, conflict management, negotiation, and meeting management” (DeSanctis et al, 2008, p. 552). They structure, store, facilitate, and distribute human communication, and aggregate views of a group of people (Ishizaka & Nemery, 2013).

Research has shown that, in general, GDSS are effective tools for generating ideas and plans (Eden & Ackermann, 2014; Power, 2002) and identifying, collecting, organizing and interpreting the thoughts of the participants (Roszkiewicz, 2007). GDSS facilitates working interactively and dynamically with collective group data. All GDSS software allows for the anonymous generation of ideas, shared and parallel input, and complete and accurate record keeping.

ISSUES AND PROBLEMS

A large technology company contracted with a Carnegie Research I university to facilitate GDSS meetings with its employees, and to conduct a case study to analyze the effectiveness of the use of GDSS for the company based on the results of the GDSS sessions. Case study is not a methodological choice but a choice of what is to be studied (Stake, 2000); here the choice was to study the impact of using the GDSS system with the company’s employees.

A GDSS system can be used virtually or with co-location of the participants. In this instance, the business involved engaged in a series of computer-mediated activities while they were co-located. Chen and Linn (2012) found that group decision-making is more effective when participants are face-to-face rather than dispersed. The GDSS meetings were conducted at a local university in one of its computer labs.

The business’ employees agreed unanimously (n=45) that using GDSS was more effective than

traditional “flip chart” meetings. They were also unanimous in finding the tool easy to use and understand. On a scale of 1-10 (10 being the best), 87% of the meeting participants rated the entire GDSS experience an 8 or higher.

When asked to identify what they particularly liked about collaborating using GDSS, the feedback was consistent among the employees. The anonymity of the input, the ability to generate many ideas in a non-threatening setting, the opportunity to stimulate participation and interaction, the ease of use of the product, and the efficiency of the use of groupware technology over more traditional forms of brainstorming meetings were the most important aspects of the GDSS experience.

Al Shishany and Adams (2013) found that anonymity plays a significant role in fostering discussions. However, Scott, Quinn, Timmerman, and Garrett (1998) found that some members of the groups they studied reported feeling frustrated at not being able to figure out who was saying what. In this particular case study, however, that desire was not expressed. Directly related to the concept of anonymity is the articulation of the computer-mediated collaborative meeting participants’ pleasure at being able to contribute in an environment they felt was non-threatening.

Using GDSS has been proven to increase user participation (Adla, Zarate, & Soubie, 2011). The use of GDSS is intended, among other things, to promote the opportunity to generate a lot of ideas from participants since they can input their thoughts using the computer without interrupting another person (Olson & Olson, 2003).

The use of GDSS in a computer-mediated collaborative meeting environment can greatly increase efficiency (Khan, 2014). As Lococo and Yen state, “Efficient sharing of ideas can be transformed into shared understanding and into shared priorities” (1998, p. 91). Participants in this particular case study concurred that the use of groupware technology was in general more efficient than traditional forms of meetings.

There was very little negative feedback regarding the actual use of GDSS in the collaboration.

The comments involved wanting a clearer understanding at the outset of the goals of the meeting, a feeling that the process was too structured, and a concern that management would not use the information generated in the session to improve the division.

The impressions of the actual meeting room environment had much more of a negative impact on the GDSS participants. On a scale of 1-10 (with 10 being the best), over 25% rated the physical environment of the lab a 6 or below. There was tremendous consistency in the feedback: the glare off the glass over the monitor made it very difficult to see the screen, the workstation ergonomics were poor and the chairs were too far apart, the ambient noise of the computers was very loud, and the room temperature was either a) too hot, or b) too cold.

SOLUTIONS AND RECOMMENDATIONS

GDSS facilitates transactional computer-mediated communication. “Transactional” implies a give-and-take situation; an interpersonal communication relationship in which parties alternate in their roles as sender, receiver, and information processor, thereby exchanging information. “Mediated” signifies that media technologies are involved. In this particular case study, the GDSS technology allowed the participants to input data into the system (sender), read the other meeting participants’ comments (receiver), and then discuss the information and come to consensus (information processor). The process helped the group understand the issues facing them (French, 2007) and produced potential solutions.

Also, it is important to note that this case study occurred in a real-life setting and not in the artificial confines of a laboratory experiment. As Gopal and Prasad state, “...technology cannot be studied outside its social context” (2000, p. 512). The collaborators were not strangers thrown together randomly, but team members who

worked together and knew each other well. The use of zero-history groups in GDSS research has been criticized (Putnam & Stohl, 1996), making the case for “the study of intact natural groups embedded in larger structures” (Scott, 1999, p. 464), as is the case here.

We would argue that the use of GDSS in a computer-mediated collaborative setting reduces the amount of entropy and noise possible while increasing the opportunity for redundancy, thereby eliminating potential barriers to effective communication.

As previously discussed, the concept of entropy has to do with the different ways a message can be constructed. Vague or ambiguous messages have a high degree of entropy. In fact, all computer-mediated communications have the potential for heightened entropy because of the nature of CMC itself. CMC relies heavily on text-based messages, which can increase the amount of ambiguity in a message (Klein, Clark, & Herskovitz, 2003) because of the environment is mediated and not face-to-face (Adla et al., 2011). There are no visual cues, no way “...of allowing the receiver to send the electronic equivalent of...an ‘uh-uh,’ or any other audio-visual reactions which play such a critical role in face-to-face interaction” (Crystal, 2001, p. 30). As Scott states, “the challenge is to understand how the technology (or distribution method) such as a computer can change the meaning of the message” (Scott, 2009, p. 28).

Anonymity, too, can increase entropy. Knowing who sent a particular message can assist the receiver in interpreting that message accurately. For example, what if the message, “we are all going to be fired from our jobs next week,” scrolls up on the screen during a GDSS session. The meaning of the message itself is quite obvious, yet there would be a great deal of uncertainty among the participants. Imagine the thoughts going through everyone’s mind! Knowing who sent that message, however, can help alleviate the uncertainty. If the participants knew the sender was a well-known company joker, the message would be interpreted as just another prank on the

joker’s part. If, however, the participants knew the sender was the president of the company, the message would be interpreted in a completely different way. However, one of the strongest features of GDSS systems is allowing the participants to communicate anonymously to promote dialog (McLeod, 2011).

Using GDSS in a computer-mediated collaborative setting encourages redundancy, which in turn reduces entropy. The software permits everyone to view the comments of all of the participants in real-time. As evidenced by the comments generated in this case study, there was a tremendous amount of redundancy. Perhaps someone’s memory was jogged when they saw a particular comment and was reminded that s/he too wanted to make just such a remark. Or maybe people wanted to make sure they entered their “me too” as well. Regardless of the rationale, GDSS affords the perfect opportunity for a considerable amount of redundancy within the computer-mediated collaborative structure.

As noted earlier, noise is interference in the transmission of a message; anything that comes along with the signal that was not originally put there by the sender. In a traditional (face-to-face) collaborative environment, there are any number of possible distractions that could be construed as noise. People interrupting each other or shouting to be heard over someone else talking would most definitely impact the receipt of a message. Noise – literally.

But the use of a GDSS to collaborate eliminates noise. Everyone is free to input as many comments as they choose without being interrupted or shouted down. The message is clear and concise and received just as the sender intended.

The specific groupware characteristics the employees identified as effective (anonymity, safe setting, brainstorming and idea generating, and efficiency) are precisely why groupware products are used by corporations in meetings and in the decision-making process (Scott, Allen, Rogelberg, & Kello, 2015). In this case study, employees were able to provide management with valuable

input in an effective and efficient manner. This is also consistent with groupware theory. The few negative comments were organizational issues and not GDSS issues.

FUTURE RESEARCH DIRECTIONS

Information theory, as originally articulated by Shannon, is linear and mechanistic (Perry, 2002). A suggestion for future research is to examine the role of GDSS in computer-mediated collaborative settings using more transactional theories and models. Another area for future research is to reexamine information theory itself with respect to more modern computer-mediated collaborative technologies such as GDSS.

CONCLUSION

GDSS can be a very powerful tool for organizations. Used properly, the technology has tremendous potential to generate ideas and assist in decision making to improve the functioning of corporations. While “the same technology will not provide the same results with each group and in each setting” (Boiney, 1998, p. 343), collaborating using GDSS has many benefits, including the reduction of entropy and noise and the increased opportunity for redundancy as predicted by information theory.

Pollock and Kanachowski (1993) define a GDSS as a system where group members use computers interactively to support the group’s decision-making capacity. The use of GDSS has also been shown to produce more creative solutions as well as increasing the commitment of participants to decisions made in the GDSS sessions (Golden & Pineo, 2014). Based on the case study results, the GDSS obviously met this particular company’s needs effectively and efficiently.

Although some research suggests there is inconclusive evidence GDSS actually facilitates computer-mediated collaboration, we believe in

this case the use of the GDSS greatly enhanced the collaborative experience. Based on the results of the case study, the company and its remote division were extremely satisfied with the results. According to Poole and Holmes (1995), the strength of GDSS comes from the technology’s ability to enhance communication and information exchange, complex information processing tasks, and coordination and organization of group activities. These strengths were evident in the results from this case study, and have very practical applications.

The information theory concepts of entropy, redundancy, and noise are highly relevant in examining computer-mediated collaborations using GDSS. The success of a GDSS intervention depends upon several different factors, including the nature of the technology used (Hiltz, Dufner, Fjermestad, Kim, Ocker, Rana, & Turoff, 2012). As the number of communication channels available expands with the diffusion of mobile devices and noise levels in organizational environments increases, using information theory is a highly relevant approach for communication scholars (Stephens et al., 2013) to understand the impact of different technologies on the communication process.

KEY TERMS AND DEFINITIONS

Communication: Human interaction with others to deliver information.

Computer-Mediated Communication: Human interaction using technological devices.

Entropy: The many different ways a message can be constructed depending on the circumstance.

Group Decision Support Systems: Technology that facilitates people working interactively and dynamically with collective group data.

Information Theory: A theory that provides the means to measure the efficiency of communication systems.

Noise: Interference that occurs in the transmission of a message.

Redundancy: Conveying the same information more than once in a message so the interpretation of the message is clear.

Evolutionary Algorithms for Global Decision Tree Induction

Marek Kretowski

Bialystok University of Technology, Poland

Marcin Czajkowski

Bialystok University of Technology, Poland

INTRODUCTION

Data mining (Fayyad, Piatetsky-Shapiro, Smyth & Uthurusamy, 1996) can reveal important and insightful information hidden in data. However, appropriate tools and algorithms are required to effectively identify correlations and patterns within the data. Decision trees (Kotsiantis, 2013) represent one of the main techniques for discriminant analysis prediction in knowledge discovery. The success of tree-based approaches can be explained by their ease of application, fast operation, and effectiveness. Furthermore, the hierarchical tree structure, in which appropriate tests from consecutive nodes are sequentially applied, closely resembles a human way of decision making. All this makes decision trees easy to understand, even for inexperienced analysts.

Despite 50 years of research on decision trees, many problems still remain (Loh, 2014) such as searching only for a locally optimal split in the internal nodes; appropriate pruning criterion, efficient analysis of cost-sensitive data or performing multi-objective optimization. To help resolve some of these problems, evolutionary algorithms (EAs) (Michalewicz, 1996) has been applied to decision tree induction (Barros et al., 2012). The strength of this approach lies in the global search for splits and predictions. It results in higher accuracy and smaller output trees compared to popular greedy decision tree inducers.

The purpose of this chapter is to illustrate the application of EAs to the problem of deci-

sion tree induction. The objectives are to show that evolutionary optimization, compared to the greedy search, may result in finding globally optimal solutions, whose complexity is significantly smaller and the prediction is highly competitive. We will cover the global induction of classification, regression, and model trees.

BACKGROUND

We may find different variants of decision trees in the literature (Loh, 2014). They can be grouped according to the type of problem they are applied to, the way they are induced, or the type of structure. Tree predictors can be used to classify existing data (classification trees) or to approximate real-valued functions (regression trees) (see Figure 1). In each leaf, classification tree assigns a class label (usually the majority class of all instances that reach that particular leaf), while the regression tree holds a constant value (usually an average value for the target attribute). A model tree can be seen as an extension of the typical regression tree (Quinlan, 1992). The constant value in each leaf of the regression tree is replaced in the model tree by a linear (or nonlinear) regression function. To predict the target value, the new tested instance is followed down the tree from a root node to a leaf using its attribute values to make routing decisions at each internal node. Next, the predicted value for the new instance is evaluated based on a regression model in the leaf.

Figure 1. An illustration of predicted values of the classification, regression, and model trees

Examples of predicted values of classification, regression, and model trees are given in Figure 1.

The gray level color of each region represents a different class label (for a classification tree), and the height corresponds to the value of the prediction function (regression and model trees).

Inducing optimal decision tree is known to be NP-complete (Naumov, 1991). Consequently, practical decision-tree learning algorithms are based on heuristics such as greedy algorithms where locally optimal splits are made in each node. The most popular tree-induction is based on the top-down approach (Rokach & Maimon, 2005). Top-down induction starts from the root node, where locally best split (test) is searched, according to the given optimality measure (e.g. Gini, towing or entropy rule for classification tree and least squared or least absolute deviation error criterion for regression tree). Next, the training instances are redirected to the newly created nodes and this process is repeated for each node until some stopping-rule is satisfied. The recursive partitioning of the dataset may lead to the data over-fitting, therefore, the decision tree pruning (Esposito, Malerba & Semeraro, 1997) is applied to improve the generalization power of the predictor. For an alternative approaches to greedy decision tree induction, like e.g. bottom-up, please refer to framework proposed by Barros et al. (2014).

Most of tree inducing algorithms partition the feature space with axis decision borders (Sheth & Deshpande, 2015). These types of trees are called univariate decision trees. Split at each non-terminal node usually involves single feature. For a continuous-valued feature usually an inequality

test with binary outcomes is applied and for a nominal attribute mutually exclusive groups of attribute values are associated with outcomes. One of the first and most well-known solution that can be applied to classification and regression problem is CART (Breiman, Friedman, Olshen & Stone, 1984) system. Good representatives of univariate inducers are also systems developed by Quinlan: C4.5 (1993) for classification and M5 (1992) for regression.

When more than one feature is taken into account to build a test in non-terminal node, then we deal with multivariate decision trees. The most common form of such a test is an oblique split, which is based on a linear combination of features (hyper-plane). The decision tree which applies only oblique tests is often called oblique or linear, whereas heterogeneous trees with univariate, linear and other multivariate (e.g., instance-based) tests can be called mixed decision trees (Llora & Wilson, 2004). It should be emphasized that computational complexity of the multivariate induction is generally significantly higher than the univariate induction. OC1 (Murthy, Kasif & Salzberg, 1994) is a good examples of multivariate decision tree system.

Inducing the decision tree with greedy strategy usually leads to suboptimal solutions. They search only for locally best splits at each node which does not guarantee the globally best solution. One of the alternatives is the ensemble of trees (Seni & Elder, 2010), which is created by the induction of different trees from the training sample. Ensemble classifiers like Random Forests (Breiman, 2001) induce many decision trees whose predictions

are combined to make the overall prediction for the forest (a collection of trees). Multiple models improve predictive performance, however, single-tree comprehensibility is lost. Different approaches propose look-ahead algorithms like APDT (Shah & Sastry, 1999) for classification and LLRT (Vogel, Asparouhov & Scheffer, 2007) for regression.

Evolutionary computing techniques are proven to be effective at escaping local optima and are able to successfully solve a general class of difficult computational problems. The global induction is mainly represented by systems based on an evolutionary approach (Barros et al., 2012; Barros, Carvalho & Freitas, 2015), however, in the literature there are some attempts of e.g. ant colony optimization algorithms (Boryczka & Kozak, 2010; Otero et al., 2012).

The global approach to decision tree induction was initially investigated in genetic programming (GP) community. The tree-based representation of solutions in a population makes this approach especially well-suited and easy for adaptation to decision tree generation. For the classification trees, the first attempt was made by Koza (1991), where author presented GP-method for evolving LISP S-expressions corresponding to simple decision trees. Next, univariate trees were evolved by Nikolaev and Slavov (1998) and Tanigawa and Zhao (2000), whereas Bot and Langdon (2000) proposed a method for induction of classification trees with limited oblique splits. Among genetic approaches for univariate decision tree induction there is GATree system proposed by Papagelis and Kalles (2001) and GAIT developed by Fu, Golden, Lele, Raghavan and Wasil (2003).

In the literature, there are relatively fewer evolutionary approaches for the regression and model trees than for the classification trees. In TARGET solution proposed by Fan & Gray (2005), authors propose to evolve a CART-like regression tree with simple genetic operators. Later solutions focus on evolving model trees with linear models: E-Motion (Barros, Duncan & Basgalupp, 2011) and non-linear models: GPMCC (Potgieter & Engelbrecht, 2008), in the leaves.

GLOBAL INDUCTION OF DECISION TREES

This section discuss the general concept of a standard evolutionary algorithm and its application for decision tree induction. It is a common algorithmic framework for both genetic algorithms (GAs) and genetic programming (GP) and can be applied to build a decision tree classifier and regression tree predictor.

Evolutionary Algorithms

Evolutionary algorithms (Michalewicz, 1996) belong to a family of metaheuristic methods which represent techniques for solving a wide variety of difficult optimization problems. They provide a general framework (see Figure 2) which is inspired by biological mechanisms of evolution. The algorithm operates on individuals which compose a current population. Each individual represents a candidate solution to the target problem. Individuals are assessed using a measure named the fitness function which measures their performance and those with higher fitness have usually higher probability of being selected for reproduction. Genetic operators such as mutation and crossover influence new generations of individuals, producing new offspring. This guided random search (offspring usually inherits some traits from its ancestors) is stopped when some convergence criteria is satisfied. Evolutionary algorithms can also be combined with local search techniques. This synergy, known as Memetic Algorithms (Chen, Ong, Lim & Tan, 2011) allows speeding up and focusing the evolutionary search.

Evolutionary Induction of Decision Tree

Evolutionary algorithms which are designed to solve difficult optimization problems can be successfully applied to the problem of decision tree induction. There are, however; a few factors that need to be consider in order to exploit the full potential of evolutionary induction.

Figure 2. A general framework of evolutionary algorithm

Representation and Initialization of Individuals

The type of EA may be identified by the way the individuals in the populations are represented. A genetic algorithm is typically considered when solutions are encoded in a fixed-length linear string. The tree-encoding schemes usually imply genetic programming (GP), where the solution encodes data and functions (Woodward, 2003), however; the border between different types of EAs is vague and debatable.

When the individual is a univariate tree, each test in a non-terminal node concerns only one attribute (nominal or continuous valued). In a case of a continuous-valued attribute typical inequality tests are applied and only precalculated candidate thresholds (Fayyad & Irani, 1992) are considered as potential splits. A candidate threshold for the given attribute is defined as a midpoint between such a successive pair of examples in the sequence sorted by the increasing value of the attribute, in which the examples are characterized by different classes (or predicted values in case of regression trees). Although this solution works better with classification problem, it still may limit the number of possible splits and focuses the search process for regression trees. For a nominal attribute at least one value is associated with each branch. It means

that an inner disjunction is built into the induction algorithm. Individuals can also be represented by the oblique decision trees with multivariate tests or mixed decision trees (Kretowski & Grześ, 2007).

In general, initial population should be generated randomly to provide enough diversity of individuals. Due to the large search space, seeding the initial population with one of greedy solutions, discussed in the chapter, can enhance the quality of the search and shorten the execution time. To prevent the EA from being trapped in local optima, initial individuals can be induced on a random subsample of the training data and the potential tests in internal nodes can be searched on a random subset of attributes.

Genetic Operators

Genetic operators are the two main forces that form the basis of evolutionary systems and provide a necessary diversity and novelty. Tree-based representation requires developing specialized operators corresponding to the classical mutation and cross-over. Application of the operators can modify the tree structure, tests in internal nodes and models in the leaves (in case of the model trees).

Crossover is inspired by the sexual reproduction of living organisms. The crossover operator attempts to combine elements of two existing in-

dividuals (parents) in order to create a new (novel) solution but with some features of its “parents”. Each crossover starts with selecting the positions (nodes) in two affected individuals. In the most straightforward variant, the subtrees starting in the selected nodes are exchanged, which corresponds to the classical crossover from genetic programming (Koza, 1991). When the non-terminal nodes are chosen and the number of outcomes is equal, tests or branches associated with randomly chosen nodes can also be exchanged.

Mutation operator, also inspired by the biological process of the same, makes random changes in some places of selected individuals. Possibilities of mutation operator depend on the node type (leaf or internal node). For a non-terminal node a few variants exist:

- Existing test can be modified or a new test of the same or different type can be selected,
- Oblique test can be simplified or an axis-parallel test can be transformed into oblique one,
- Node can be transformed (pruned) into a leaf,
- One sub-tree can be replaced by another sub-tree from the same node.

Leaf modification makes sense only if it contains instances from different classes (or different predictive values). The leaf is transformed into an internal node and a new test is randomly chosen. More mutation variants for the leaf can be applied to the model trees. Linear model in the leaf can be extended, simplified or changed by adding, removing or replacing randomly chosen attributes.

Additional local search components can be built into the mutation-like operator. Memetic extension can be used to search for the split in the internal node, for example to find locally optimal test on given attribute or shift the splitting threshold at continuous-valued feature. While performing mutation in the leaves of the model

trees, the multivariate linear regression models can also be locally optimized (Czajkowski & Kretowski, 2012).

Fitness Function

Selection acts as a force which increases the quality of the population. For this reason, mechanism of selection usually requires a quantitative measure to assess individuals in the population. Such an objective function is called a fitness function and in practice it is a very important and sensitive element of the evolutionary system. It drives the evolutionary search process by measuring how good a single individual is in terms of meeting the problem objective.

In context of decision trees a direct minimization of the prediction performance measured on the learning set usually leads to the over-fitting problem and poor performance on unseen, testing observations, because the trees are overgrown. Therefore, we need to balance the reclassification quality (classification tree) or predictive error (regression tree) and the complexity of the tree.

For the classification trees an idea that is similar to the one used in cost complexity pruning in the CART system (Breiman et al., 1984) can be applied. The fitness function that is maximized can have the following form:

$$Fitness(T) = Pred(T) - \alpha * (Comp(T) - 1.0),$$

where $Pred(T)$ is usually equal the reclassification quality (Kretowski & Grześ, 2005) of the tree T and α is the relative importance of the predictor complexity. In the simplest form the tree complexity $Comp(T)$ can be defined as the tree size which is usually considered to be the number of nodes. The penalty associated with the classifier complexity increases proportionally with the tree size and prevents over-fitting. Subtracting the value 1.0 eliminates the penalty when the tree is composed of only one leaf. This general form of

the fitness function can be adjusted to different requirements. The term $Comp(T)$ can be modified to reflect not only the number of nodes but also the complexity of the tests.

In case of regression and model trees, the statistical model-selection criteria that are based on likelihood (e.g. AIC proposed by Akaike (1974) or BIC proposed by Schwarz (1978)) works well as fitness functions (Fan & Gray, 2005). These measures of goodness of fit penalize the model complexity (size of the tree). There are some resemblances in general formula of information criteria with the one from CART system as both construct a weight formula. The $Pred(T)$ is based on the maximum of the likelihood function and the term $Comp(T)$ can also be viewed as a penalty for overparametrization. For both information criteria, the penalty term depends not only on the predictor size but also on the number of observations. In case of multivariate trees, the penalty term may also be adjusted to take into account the number of attributes in the internal nodes and the size of the regression model in the leaves (for the model trees).

In addition, many fields like for example medicine or finance need to take into account, besides prediction error, the costs of features (due to costly measurements) or misprediction-cost (due to costs of wrong decision). The term cost-sensitive is used in the field (Turney, 1995) for the classification problem and the recent survey of cost-sensitive decision tree induction algorithms is available (Lomax & Vadera, 2013). The modification of the fitness function allows selecting features in accordance to their cost and optimizing the misprediction cost instead of the prediction error.

SOLUTIONS AND RECOMMENDATIONS

This section briefly recalls the Global Decision Tree (GDT) system whose general structure fol-

lows a typical EA framework (Michalewicz, 1996) with an unstructured population and a generational selection. Its framework can be used for the evolutionary induction of all types of trees: classification, regression and model (Kretowski & Grześ, 2007, Czajkowski & Kretowski, 2014). Among a family of tree inducers with homogeneous tree representations (univariate, multivariate, regression and model), the GDT system is capable of inducing heterogeneous trees (Czajkowski & Kretowski, in press). Such mixed decision tree can self-adapt its nodes representation to the currently analyzed data during the evolutionary induction.

The GDT solution concept can be applied in many real-life applications, such as finance (Czajkowski & Kretowski, 2015) and medicine (Grześ & Kretowski, 2007). The cost-sensitive approach of GDT is also available as well as various multi-objective optimization strategies that base on a weight formula and lexicographic analysis. Finally, to improve the performance of GDT system a hybrid MPI+OpenMP parallel implementation for classification (Czajkowski, Jurczuk & Kretowski, 2015) and regression/model trees (Czajkowski & Kretowski, 2016) was also proposed.

FUTURE RESEARCH DIRECTIONS

There are a number of promising directions for future research. In particular, there is always a strong motivation for speeding the evolutionary induction of decision trees up. Application of new parallel frameworks like CUDA (Strnad & Nerat, 2016) or Hadoop (White, 2009) is especially important in the context of modern data mining applications, where huge learning sets and the big data need to be analyzed. Another possibility of speeding up and focusing evolutionary search is application of the self-adaptive parameters in EA. Researchers should start to establish the relationship between EAs' parameter settings and dataset features.

Different multi-objective optimization strategies should also be considered like the Pareto-dominance approach. Finally, there are many challenges with application global decision trees for spatio-temporal, streaming datasets or for survivor and risk analysis.

CONCLUSION

In this chapter, the global induction of classification and regression trees is presented. Specialized genetic operators and memetic extensions impact the structure of the predictor, tests in internal nodes and, in case of model trees: regression planes in the leaves. Suitable defined fitness function allows focusing the search process and efficiently generating competitive predictors.

Every approach has drawbacks and limitations, however, in this particular case these drawbacks are well known and easily understood. Firstly, globally induced decision trees are obviously slower than greedy counterparts. Secondly, the one, final solution is not guaranteed as the evolution process will tend to run on indefinitely (if the predefined ending condition is not specified). On the other side, because the evolutionary process is progressive, intermediate answers can be harvested at practically any time. The most important is, however, the fact, that globally induced decision trees are able to avoid local optima, evolved trees are significantly smaller, less complex and usually generate better predictive model, also in terms of predictive accuracy, than the greedy counterparts.

KEY TERMS AND DEFINITIONS

Classification Tree: A decision tree applied to the classification problem, where each leaf node is labeled with one class label. Classification tree is used to predict membership of cases or instances in the classes of a categorical dependent variable from their measurements on one or more predictor variables.

Decision Tree: A decision tree is a graph that uses a branching method to illustrate every possible outcome of a decision. Each branch of the decision tree represents a possible decision or occurrence. The tree structure shows how one choice leads to the next, and the use of branches indicates that each option is mutually exclusive.

Decision Tree Pruning: An approach that reduces the size of decision tree by removing parts of the tree that provide little power to classify/predict the data. This technique improves the generalization power of the decision tree and reduces the over-fitting.

Global Induction: A method of decision tree generation, where both the tree structure and all tests are searched at the same time; usually based on evolutionary approach in contrast to top-down induction.

Mixed Decision Tree: A decision tree with heterogeneous representation. The tests in internal nodes may be univariate or multivariate whereas the leaves may hold a constant value or a regression model.

Model Tree: An extension of regression trees where the constant value in the terminal node is replaced by the regression plane.

Multivariate Decision Tree: A decision tree with tests involving several attributes. The most common form of such tests is an oblique split, which is based on a linear combination of features (hyper-plane).

Regression Tree: A decision tree applied to the regression problem, where the dependent variable is continuous. Each leaf of the tree usually holds a constant value (usually an average for the target attribute of all instances that reach this particular leaf).

Top-Down Induction: A recursive method of decision tree generation. It starts with the entire input dataset in the root node where a locally optimal test for data splitting is searched and branches corresponding to the test outcomes are created. The test searches and data splitting are repeated in the created nodes unless the stopping condition is met.

Univariate Decision Tree: A decision tree which partitions the feature space with axis-parallel hyper-planes. Each split at non-terminal node involves single feature.

A Family Review of Parameter–Learning Models and Algorithms for Making Actionable Decisions

Chun-Kit Ngan

The Pennsylvania State University, USA

INTRODUCTION

Learning optimal decision parameters over time series (Bisgaard & Kulahci, 2011; Chatfield, 2001) to make actionable recommendations is an important topic which has gained significant interest in the past decade. In financial markets, stock investors analyze economic indicators to predict the occurrence of a bear market bottom or a bull market top to determine when they should buy or sell their stocks in order to gain the maximal profit. In medical diagnosis, physicians measure diabetes patients' blood-glucose-level (BGL) threshold to detect when the patients suffer hypo- and hyperglycemia. In energy industry, microgrid engineers investigate electricity peak demands to decide when the load shedding of electric power within the microgrid should be executed in order to minimize energy costs and maximize customers' savings while preserving the desired quality of service (QoS) in terms of power interruption. The goal of these time-series data analyses is to enable domain experts to understand the problems and lead them into a better decision-making and actionable recommendation.

Consider one particular example above that the stock investors are interested in determining when a bear market bottom will occur so that they can buy the stocks in the lowest price and then sell the stocks in the future to gain the maximal profits. To achieve this purpose, financial specialists suggest that a bear market bottom (Stack, 2009) has occurred if some changes of the financial indexes, such as the S&P 500 falls at least 20% and the Consumer Confidence Index declines at

least 30 points, are detected. Note that these decision parameters, e.g., 20% and 30 points, may be given by the domain experts or learned from the formal mathematical computations. To support such a decision-making event, it is important for domain experts to develop a data analytical methodology that is reliable and useful for their decision-making. The main challenge in such a methodology is how accurately, expressively, and effectively to model, analyze, and compute those time series data such that domain experts can analytically learn the optimal parameters to make a better decision. This is exactly the focus of this chapter.

BACKGROUND

To support the above decision-making events, there are two approaches, i.e., qualitative and quantitative, that data analysts often use to help domain experts learn optimal decision parameters. A qualitative analysis is a domain-knowledge-based approach that requires domain experts to base upon their past experience and observation to analyze scenarios, from which the experts determine the decision parameters. For example, in the stock market, financial specialists have identified a set of stock indicators that can be used to determine the bear market bottom. The indicators include the S&P 500 percentage decline (SPD), Coppock Guide (CG), Consumer Confidence Index drop (CCD), ISM Manufacturing Survey (ISM), and Negative Leadership Composite "Distribution" (NLCD). If these indicators satisfy the

DOI: 10.4018/978-1-5225-2255-3.ch186

pre-defined, parameterized conditions, e.g., $SPD < -20\%$, $CG < 0$, etc., it signals that the best period for the investors to buy the stocks, e.g., the S&P 500 Index Fund, is approaching. Often these parameters may reflect some realities since they are set by the domain experts based on their past experiences, observations, intuition, and domain knowledge. However, the suggested parameters may not always be accurate because those parameters are static, but the scenarios that the experts deal with are always dynamic in nature. Thus data analysts need to develop a class of mathematical models and algorithms that can be used to help the domain experts learn the decision parameters dynamically to fit the need of these scenarios.

A quantitative analysis is a machine-learning-based approach (Bell, 2014) that enables data analysts to apply mathematical models and algorithms to learn parameters on a large amount of datasets for decision making. For instance, the logistic regression models (Bierens, 2008; Cook, et. al., 2000; Dougherty, 2011; Hansen, 2014; Heij, et. al., 2004; Rawlings, et. al., 2012; SL, et. al., 2014) are often used to predict the occurrence of an event (0 or 1) by learning parametric coefficients of the logistic distribution function of the explanatory variables. This is done based upon the historical data by applying nonlinear regression models and the Maximum Likelihood Estimation (MLE) (Myung, 2003). However, using the machine-learning-based approach to learn parameters is computationally complicated and time consuming because each dataset has a large number of attributes (i.e., the curse of dimensionality) (Bellman, 2003 and 2015) that require the data analysts to take a long time to select the significant ones before they can do the parameter learning. Hence domain experts' knowledge is necessary to help the analysts identify and select the significant attributes to avoid the curse of dimensionality before learning the parameters.

Thus this chapter addresses the approach to close the above research gaps. More specifically, the chapter addresses the following two research questions:

1. How to develop the “time-point-based” mathematical models and learning algorithms that combine the strengths of both qualitative and quantitative approaches to learn optimal decision parameters to make actionable recommendations.
2. How to implement the experimental case studies that evaluates the performance of these developed hybrid-based parameter-learning models and algorithms.

HYBRID-BASED PARAMETER-LEARNING MODELS AND ALGORITHMS

To answer the above research questions, the authors have developed a family of parameter-learning models and algorithms, i.e., Expert Query Parametric Estimation (EQPE) models and Checkpoint algorithms (Ngan, et. al., 2010, 2011, 2012 & 2013), which combines the strength of both qualitative and quantitative methodologies to complement each other to learn optimal decision parameters in an efficient manner. This family of models and algorithms relies on domain expertise to select attributes and conditions against the data, from which the family of EQPE models and Checkpoint algorithms can learn decision parameters efficiently. This class of models and algorithms can be divided into two categories: Single-Event (SE) and Multi-Event (ME). The SE-EQPE model, using the Checkpoint algorithm, learns one decision parameter to detect the occurrence of a single event, e.g., the bear market bottom or the bull market top. The ME-EQPE model is the further extension of the SE-EQPE model, using the (Multidimensional) M- or (Relaxed) R-Checkpoint algorithm, to learn multiple decision parameters simultaneously to detect the occurrence of multiple events in sequence, e.g., the bear market bottom and then the bull market top. More specifically, the M-Checkpoint algorithm is a brute-force approach that learns multiple decision parameters optimally at their inter-related time points for multi-events.

This approach should be used if the data analysts focus on learning the optimal decision parameters and do not need to concern about the high time complexity and computational cost. Oppositely, the R-Checkpoint algorithm is a heuristic methodology that learns multiple decision parameters, which are fairly close to the optimal parameters learned from the M-Checkpoint algorithm, and maintains a satisfactorily low time complexity. This approach should be adopted if the data analysts emphasize on learning the reasonably good parameters in a shorter time.

However, the family of the above EQPE models and Checkpoint algorithms has two important issues. First the models and the algorithms only solve the problems that can solely take the real-value time series, whereas some other specific problems may need the binary time series as the inputs to signal the occurrence of some events. Second the models and the algorithms only consider the conjunctive constraints but cannot solve the specific problems that require the considerations of disjunctive and biconditional constraints.

Consider one example again that the physicians measure diabetes patients' BGL threshold to detect when the patients suffer hypo- and hyperglycemia (American Diabetes Association, 2014 & 2015). First to determine the BGL detection threshold, the binary time series that signals the symptoms of hypo- and hyperglycemia is needed. Second

when the diabetes patients' BGLs are higher or lower than the given threshold, the patients may start suffering at least one or more symptoms of hypo- or hyperglycemia respectively but probably not all. These symptomatic conditions are indeed disjunctive binary constraints, which are used to evaluate whether or not the symptoms of hypo- or hyperglycemia occur in the diabetes patients. Third to make certain the hypo- or hyperglycemic symptoms occurred due to the monitoring constraints satisfied, i.e., the diabetes patients' BGLs lower or higher than the given threshold, and vice versa, biconditional constraints are needed. For instance, if a patient suffers from fatigue, dizziness, confusion, headaches, blurred vision, etc., it implies that the patient's BGL drops below or exceeds above the threshold not because of other illnesses. Similarly, if the patient's BGL becomes lower or higher than the threshold, it implies that he or she suffers from the hypo- or hyperglycemic symptoms. To solve this specific type of problems, the authors have further extended their previous SE model and algorithm to develop the (Hypoglycemic) H-EQPE model and the Linear L-Checkpoint algorithm (Ngan & Li, 2015) to learn one BGL threshold to detect the occurrence of hypoglycemia. Based on the H-EQPE and the ME-EQPE models, the authors further developed the (Glycemic) G-EQPE model to learn the two BGL thresholds to detect the occurrence of both

Figure 1. A family of parameter-learning models and algorithms: EQPEs and checkpoints

hypo- and hyperglycemic events in sequence. Figure 1 demonstrates the relationships among all the developed EQPE-based models and Checkpoint-oriented algorithms.

To show the effectiveness and the efficiency of the developed models and algorithms shown in Figure 1, the authors compare their methods with the domain-knowledge-based and the machine-learning-based approaches. As a proof of concept, the authors have conducted the two experimental case studies, i.e., the stock market and the glycemia, respectively. The authors show that their approaches are more effective and produce the results that are superior to those of the two other approaches mentioned above. More specifically, in their experiments, the authors find that their algorithms outperform the domain experts' recommendations and the logistic regression models.

The rest of the chapter is organized as follows. In the fourth section, the authors describe their SE-EQPE model and the Checkpoint algorithm with the "Stock Market Case Study" results in detail. Using the same case study as an example, the authors illustrate how to formulate the ME-EQPE problem and illustrate the performance of their *M-/R-Checkpoint* algorithms in the fifth section. In the sixth section, the authors demonstrate the formulation of the H-EQPE and G-EQPE models with the "Hypo- and Hyperglycemia Case Studies" results using the *L-Checkpoint* algorithm. In the seventh section, two prospective applications that are solved by the models and algorithms are described. The eighth and ninth section briefly summarizes the future work and concludes the chapter respectively.

SE-EQPE MODEL AND CHECKPOINT ALGORITHM

The goal of a SE-EQPE problem is to find optimal values of decision parameters that maximize an objective function over historical time series. For a SE-EQPE problem being constructed, the authors need to define a model for it. The authors assume

that the time domain $\mathbf{T}$ is represented by a set of natural numbers: $\mathbf{T} = \mathbf{N}$, and that the authors are also given a vector of n real-valued parameter variables $(p_1, p_2, \dots, p_n)$.

Single-Event Expert Query Parametric Estimation (SE-EQPE) Problem: A SE-EQPE problem is a tuple $\langle S_M, P_M, C_M, U \rangle$, where $S_M = \{S_1, S_2, \dots, S_k\}$ is a set of k parametric monitoring time series, $P_M = \{p_1, p_2, \dots, p_n\}$ is a set of n real-value monitoring parametric decision variables, C_M is a parametric monitoring constraint in S_M and P_M , and U is a time utility function.

Single-Event Expert Query Parametric Estimation (SE-EQPE) Solution: A solution to the SE-EQPE problem $\langle S_M, P_M, C_M, U \rangle$ is $\argmax O(p_1, p_2, \dots, p_n)$, i.e., the values of monitoring parameters, $p_1, p_2, \dots, p_n$, that maximize O , where O is the objective function corresponding to U .

To solve the SE-EQPE problem means to find the optimal values of decision parameters $p_1, p_2, \dots, p_n$ to maximize $O(p_1, p_2, \dots, p_n)$. The optimal values of decision parameters $p_1, p_2, \dots, p_n$ can be determined by using the Checkpoint algorithm.

The Checkpoint algorithm uses a KD tree data structure and a searching algorithm (Bentley, 1975 & 1979; Samet, 2006) to find the optimal decision parameters. The details of the algorithm can be found in (Ngan et. al., 2010 & 2011).

Theorem 1: For N parameter vectors in the dataset, the Checkpoint algorithm correctly computes a SE-EQPE solution, i.e., $\argmax O(p_1, p_2, \dots, p_k)$, where O is the objective function of the SE-EQPE problem, with the complexity $O(kN \log N)$.

Stock Market Case Study

The authors assume that the investor buys the S&P 500 index fund at the decision variable time t and sell it at the given t_s , which is the last day of the given training data set. The earning function $SP(t_s)/SP(t) - 1 \in \mathbf{R}$ is the utility, which is maximized by choosing the optimal value $t \in \mathbf{T}$, where $SP(t_s)$ and $SP(t)$ are the sell and buy value

Table 1. Time-series data

Table 2. SE-EQPE problem and solution formulation for the S&P 500 index fund

Problem: $\langle S_M, P_M, C_M, U \rangle$, where $S_M = \{SPD, CG, CCD, ISM, NLCD\}$ $P_M = \{p_1, p_2, p_3, p_4, p_5\}$ $C_M = SPD(t) < p_1 \wedge CG(t) < p_2 \wedge CCD(t) < p_3 \wedge ISM(t) < p_4 \wedge NLCD(t) > p_5$ $U = SP(t_s)/SP(t) - 1$ Solution: $\operatorname{argmax} O(p_1, p_2, p_3, p_4, p_5) \triangleq U(t)$

of the S&P 500 index fund at the time t_s and t respectively. The SE-EQPE problem and solution for the stock market case study can be constructed by putting the considered time series, parameters, constraints, and functions to the definitions shown in Table 1 and 2.

The values of the optimal decision parameters can be determined by using the Checkpoint algorithm. Using the Checkpoint algorithm, the authors can obtain the optimal decision parameters (i.e., -29.02, -20.01, -26.61, 49, 70) and the maximal earning (i.e., 53.37) from the training dataset for the stock market case study. The time complexity of the MLE for the logistic regression model is $O(k^2N)$, where k is the number of decision parameters, and N is the size of the learning dataset. For the Checkpoint algorithm, the complexity is $O(kM \log N)$. Using the decision parameters from the financial expert (i.e., -20%, 0, -30, 45,

180 days), the logistic regression model, and the Checkpoint algorithm, the “Best Buy” opportunities in stock and their earnings are shown in Table 3. Note that the Checkpoint algorithm considerably outperforms both the financial expert’s criteria and the logistic regression model.

ME-EQPE MODEL AND M-/R-CHECKPOINT ALGORITHM

For solving the formulations which the utility is determined from the multiple time points, a ME-EQPE model is proposed. The model assists users in finding optimal values of decision parameter vectors that maximize an objective function and satisfy their corresponding parametric constraints over historical, multivariate time series. Using the “Stock Market Case Study” as an example,

the authors illustrate how to formulate the ME-EQPE model and illustrate the performance of their M -/ R -Checkpoint algorithms in this section. The detail of the model and both of the algorithms can be found in (Ngan, et. al., 2012 & 2013). The ME-EQPE problem and solution for the stock market case study can be constructed by putting the considered time sequence vectors, parameter vectors, constraints, and functions to the definitions shown in Table 4 and 5.

The values of the optimal decision parameters can be determined by using the learning algorithms, M - and R -Checkpoint algorithm. The time complexity of the MLE for the logistic regression model is $O(mk2^N)$, where m is the number of

events, k is the number of parameteric coefficients, and N is the size of the learning dataset. For the R -Checkpoint algorithm, the complexity is $O(QkN \log N)$, where Q is the total number of m -event, time-point combinations which yields the top- Q time utility U in the learning dataset. Using the logistic regression model and the R -Checkpoint algorithm, the “Best Buy” and “Best Sell” opportunities in this investment and their earnings are shown in Table 6. The results show that the earning obtained from the logistic regression methodology is 0.52% and from the R -Checkpoint is 8.68% that is almost 17 times higher than the earning obtained from the logistic regression approach. On the contrary, even if the

Table 5. ME-EQPE problem and solution formulation for the S&P 500 index fund

Problem: $\langle S_M, P_M, C_M, U \rangle$, where $S_M = \{ \vec{S}_1(t_1), \vec{S}_2(t_2) \}$, for $\vec{S}_1(t_1) = (\text{SPD}(t_1), \text{CG}(t_1), \text{CCD}(t_1), \text{ISM}(t_1), \text{NLCD}(t_1))$ and $\vec{S}_2(t_2) = (\text{SPI}(t_2), \text{CG}(t_2), \text{CCI}(t_2), \text{ISM}(t_2), \text{NLCSV}(t_2))$ $P_M = \{ \vec{P}_1, \vec{P}_2 \}$, for $\vec{P}_1 = (p_1, p_2, p_3, p_4, p_5)$ and $\vec{P}_2 = (q_1, q_2, q_3, q_4, q_5)$ $C_M = \{ C_{M_1}, C_{M_2} \}$, for $C_{M_1} = \text{SPD}(t_1) < p_1 \wedge \text{CG}(t_1) < p_2 \wedge \text{CCD}(t_1) < p_3 \wedge \text{ISM}(t_1) < p_4 \wedge \text{NLCD}(t_1) > p_5$ and $C_{M_2} = \text{SPI}(t_2) \geq q_1 \wedge \text{CG}(t_2) \geq q_2 \wedge \text{CCI}(t_2) \geq q_3 \wedge \text{ISM}(t_2) \geq q_4 \wedge \text{NLCSV}(t_2) > q_5$ $U = f_2(t_2) * f_1(t_1) - 1$, for $f_2(t_2) = \text{SP}(t_2)$ and $f_1(t_1) = \frac{1}{\text{SP}(t_1)}$
Solution: $\text{argmax } O(\vec{P}_1, \vec{P}_2) \triangleq U(t_1, t_2)$

Table 6. Investors' earning of the S&P 500 index fund from the test data set²

Decision Approach	Best Buy	S&P 500 Index	Best Sell	S&P 500 Index	Earning%
Logistic Regression Model	10/14/08	998.01	09/03/09	1003.24	0.52%
M-Checkpoint Algorithm	10/31/08	968.75	09/07/10	1091.84	12.71%
R-Checkpoint Algorithm	10/06/08	1056.89	09/24/10	1148.67	8.68%

* The financial experts do not provide the decision parameters that can be used to determine the "Best Buy" and "Best Sell" opportunity in the sequence of occurrence.

M-Checkpoint algorithm can guarantee the optimality and yield a better earning, i.e., 12.71%, from the testing data set, but the efficiency of the R-Checkpoint algorithm, i.e., $O(QkN \log N)$, is much better than that of the M-Checkpoint algorithm, i.e., $O(N^m)$.

H-/G-EQPE MODEL AND LINEAR L-CHECKPOINT ALGORITHM

In this section, the authors demonstrate the formulation of the H-EQPE and G-EQPE models with the "Hypo- and Hyperglycemia Case Studies" results using the L-Checkpoint algorithm. The L-Checkpoint algorithm uses a two-stage approach: (1) a simple linear search to eliminate all the time points that do not satisfy a set of all binary-value symptoms and (2) a KD tree data structure and a searching algorithm to find the optimal decision parameters.

H-EQPE Model

First the authors formulate the H-EQPE problem in the case study of detecting the symptomatic events of hypoglycemia that are shown in Table 7.

Here is a brief explanation of Table 7. The H-EQPE problem can be formed by: (1) S_M - a set of one parametric monitoring time series (i.e., BGL(t) for blood glucose level); (2) S_B - a set of five binary symptomatic time series (i.e., F(t) for fatigue, D(t) for dizziness, C(t) for confusion, H(t) for headaches, and BV(t) for blurred vision); (3) P_M - a set of one monitoring parametric decision variables (i.e., p_l - a threshold of blood glucose level); (4) P_B - a set of five binary-value symptomatic conditions (i.e., $p_1', p_2', p_3', p_4', p_5'$ with either true or false value for fatigue, dizziness, confusion, headaches, and blurred vision, respectively); (5) C_G - a biconditional global constraint meaning that a patient's blood glucose level at time point t is no higher than the threshold p_l if

Table 7. H-EQPE problem and solution formulation for detecting the symptomatic events of hypoglycemia

Problem: $\langle S_M, S_B, P_M, P_B, C_G, U \rangle$, where $S_M = \{BGL(t)\}$ $S_B = \{F(t), D(t), C(t), H(t), BV(t)\}$ $P_M = \{p_l\}$ $P_B = \{p_1', p_2', p_3', p_4', p_5'\}$ $C_G = BGL(t) \leq p_l \leftrightarrow (F(t) = p_1' \vee D(t) = p_2' \vee C(t) = p_3' \vee H(t) = p_4' \vee BV(t) = p_5')$ $U = \sum_{t'=t_s}^{t_E} U'(t')$ Solution: $\text{argmax } O(p_l) \underline{\text{def}} U(t)$
--

and only if the patient is suffering at least one hypoglycemia symptomatic events (i.e., fatigue, dizziness, confusion, headaches, blurred vision); and (6) U - a time utility function that calculates the sum of the symptomatic events of hypoglycemia occurred in a time period (from t_s - the first time point, to t_e - the last time point when the patient suffers from the hypoglycemic events). To solve the H-EQPE problem means to find the optimal value of decision parameter p_i to maximize $O(p_i)$ - the objective function. The optimal value of decision parameter p_i can be determined by using the learning algorithm, i.e., L -Checkpoint.

G-EQPE Model

To learn both hypo- and hyperglycemic alarm thresholds in sequence, the authors developed the G-EQPE model that is further extended from the H-EQPE and ME-EQPE models.

The authors construct the formulation of the G-EQPE problem and solution, shown in Table 8 and 9, for detecting the symptomatic events of both hypo- and hyperglycemia in sequence.

The values of the optimal detection parameters (i.e., p and q) can be determined by using the L -Checkpoint algorithm. Based on the threshold set by the medical experts, the logistic regression

model, and the L -Checkpoint algorithm, the performance evaluation for detecting the hypo- and hyperglycemic events from the testing dataset is shown in Table 10. Note that the L -Checkpoint algorithm considerably outperforms the medical experts' criteria and the logistic regression model. From the results, the authors find that the accuracy of the L -Checkpoint algorithm is higher than that of the medical experts' criteria and the logistic regression model respectively. The L -Checkpoint algorithm also obtains the sensitivity that is higher than that of the medical experts' criteria and the logistic regression model respectively. The L -Checkpoint algorithm has a satisfactory specificity as well, which is almost the same as that of the other two approaches.

PROSPECTIVE APPLICATIONS

In addition to the above case studies, the models and the algorithms can be applied to other domains. In this section, the authors briefly describe two other problems that the models and algorithms can be used.

Bradycardia and Tachycardia Detection

A normal person's typical heartbeat rate is between 60 and 100 beats a minute. If the heartbeat rate is less than 60 or greater than 100 beats per minute, a person may suffer bradycardia and tachycardia respectively. However, different persons may have different health conditions, so this typical range cannot be applied to every individual. In order to solve this problem, the EQPE-based models and the Checkpoint-oriented algorithms can be used to learn the thresholds for detecting the occurrence of these two events respectively.

Electric Power Load Shedding

Population growth and economic development are among the key factors that lead to a higher total

Table 8. Time series in detecting the symptomatic events of hypo- and hyperglycemia

Time Series	Abbreviation
Blood Glucose Level	BGL(t)
Fatigue	F(t ₁)
Dizziness	D(t ₁)
Confusion	C(t ₁)
Headaches	H(t ₁)
Blurred Vision	BV(t ₁)
Excessive Thirst	ET(t ₂)
Leg Cramps	LC(t ₂)
Rapid Pulse	RP(t ₂)
Frequent Urination	FU(t ₂)
Dry Mouth	DM(t ₂)

Table 9. G-EQPE problem and solution formulation for detecting the symptomatic events of hypo- and hyperglycemia

Problem: $\langle S_M, S_B, P_M, P_B, C_G, U \rangle$, where $S_M = \{ \vec{S}_1(t_1), \vec{S}_2(t_2) \}$, for $\vec{S}_1(t_1) = \text{BGL}(t_1)$ and $\vec{S}_1(t_2) = \text{BGL}(t_2)$ $S_B = \{ \vec{S}_1'(t_1), \vec{S}_2'(t_2) \}$, for $\vec{S}_1'(t_1) = (F(t_1), D(t_1), C(t_1), H(t_1), BV(t_1))$ and $\vec{S}_2'(t_2) = (ET(t_2), LC(t_2), RP(t_2), FU(t_2), DM(t_2))$ $P_M = \{ \vec{P}_1, \vec{P}_2 \}$, for $\vec{P}_1 = (p)$ and $\vec{P}_2 = (q)$ $P_B = \{ \vec{P}_1', \vec{P}_2' \}$, for $\vec{P}_1' = (p_1', p_2', p_3', p_4', p_5')$ and $\vec{P}_2' = (q_1', q_2', q_3', q_4', q_5')$ $C_{G_1} = \{ C_{G_1}, C_{G_2} \}$, for $C_{G_1} = \text{BGL}(t_1) \leq p \leftrightarrow (F(t_1) = p_1' \vee D(t_1) = p_2' \vee C(t_1) = p_3' \vee H(t_1) = p_4' \vee BV(t_1) = p_5')$ and $C_{G_2} = \text{BGL}(t_2) \geq q \leftrightarrow (ET(t_2) = q_1' \vee LC(t_2) = q_2' \vee RP(t_2) = q_3' \vee FU(t_2) = q_4' \vee DM(t_2) = q_5')$ $U = \sum_{t^{(1)}=t_s}^{t_E} U^{(1)}(t^{(1)}) + \sum_{t^{(2)}=t_s}^{t_E} U^{(2)}(t^{(2)})$ Solution: $\text{argmax } O(\vec{P}_1, \vec{P}_2) \underline{\text{def}} U(t_1, t_2)$
--

Table 10. Performance evaluation for the detection of hypo- and hyperglycemic events from the testing dataset

Decision Approach	Accuracy	Sensitivity	Specificity
Medical Expert's Criteria - 70 mg/dL	85.50%	47.90%	100.00%

Decision Approach	Accuracy	Sensitivity	Specificity
Medical Expert's Criteria - 200 mg/dL	88.96%	73.46%	100.00%
Logistic Regression Model - (-23.205, 0.074)	61.92%	52.12%	68.89%
L-Checkpoint Algorithm - 172 mg/dL	99.34%	98.42%	100.00%

electricity consumption and a peak demand usage which result in a rising energy cost to consumers, as it is more expensive to generate electric power for the peak demand. Thus to learn an optimal peak demand bound over historical and projected electric power demands is necessary. As the demand usage exceeds the bound, some electricity loads are shed by shutting down some electric ac-

count units so that the peak demand charge can be controlled. Thus this optimal peak demand bound can be used to monitor the prospective demand usage in any time interval in order to minimize energy costs and maximize customers' savings while preserving the desired quality of service (QoS) in terms of power interruption.

FUTURE RESEARCH DIRECTIONS

One important issue is that the EQPE-based models and the Checkpoint-oriented algorithms are only able to solve the binary decision-making problems, e.g., buy or sell a stock, suffer from hypo- or hyperglycemia, etc. However, there are still many open scenarios, which involve in multiple decision outcomes, for example, how to determine the status of a fetal heart rate, which could be *Normal*, *Suspect*, or *Pathologic*. This is the future work that the authors will explore in their research team.

CONCLUSION

In this chapter, the authors describe and explain a family development of the parameter-learning models and algorithms: EQPEs and Checkpoints. This class of models and algorithms combines the strength of both qualitative and quantitative methodologies to complement each other to learn optimal decision parameters in an efficient manner to make actionable recommendations. To demonstrate the effectiveness and the efficiency of the models and algorithms, the authors have conducted the two experimental case studies, i.e., the stock market and the glycemia, respectively. The authors show that their approaches are more effective and produce the results that are superior to those of the two other approaches mentioned above.

KEY TERMS AND DEFINITIONS

Checkpoint Algorithm: An algorithm to learn one decision parameter to detect the occurrence of a single event.

Glycemic Expert Query Parametric Estimation Model: A model to learn two blood-glucose-level (BGL) thresholds to detect the occurrence of both hypo- and hyperglycemia in sequence.

Hypoglycemic Expert Query Parametric Estimation Model: A model to learn one blood-glucose-level (BGL) threshold to detect the occurrence of hypoglycemia.

Linear L-Checkpoint Algorithm: An algorithm to learn one blood-glucose-level (BGL) threshold to detect the occurrence of hypoglycemia.

Multi-Event Expert Query Parametric Estimation Model: A model to learn multiple decision parameters simultaneously to detect the occurrence of multiple events in sequence.

Multidimensional M-Checkpoint Algorithm: A brute-force algorithm to learn multiple decision parameters optimally at their inter-related time points for multi-events.

Relaxed R-Checkpoint Algorithm: A heuristic algorithm to learn multiple decision parameters, which are fairly close to the optimal parameters learned from the M-Checkpoint algorithm, and to maintain a satisfactorily low time complexity.

Single-Event Expert Query Parametric Estimation Model: A model to learn one decision parameter to detect the occurrence of a single event.

ENDNOTES

Informed Decision Making With Enterprise Dynamic Systems Control

Sérgio Luís Guerreiro

Instituto Superior Técnico, University of Lisbon, Portugal & INESC-ID, Portugal

INTRODUCTION

The information systems (IS) are designed, implemented and managed using abstractions layers to cope with the huge organizational complexity that is nowadays posed and also to facilitate the discussion between the different stakeholders of an organization (Laudon & Laudon, 2012) that have diverse perspectives and interpretations of it. Those discussions drive to the classical requirements elicitation stage that aims at identifying the best short-, mid- or long-term models to view, understand and operate the organization and to facilitate the forthcoming IS transformations. In this line, abstraction is a powerful intellectual tool that, in a given instant in time and context, allows to leave some other details for further analysis. In the subsequent instants of time and contexts, the abstraction level decreases and forces the stakeholders to further specify the models. Accordingly, Hoogervorst (2009) explains that business processes models are the result of applying design constraints for a particular organizational reality, which recalls to useful abstractions in order to share a common understanding between the stakeholders that have diverse interpretation of it. In fact, in the IS domain, business processes models (OMG, 2013; Archimate, 2015) are frequently used to describe the way that operations are expected to happen while the actors perform their activities. However, the business transaction models *per se*, are not sufficient and do not guarantee that the business actors perform them accordingly during operation. This unconformance phenomenon (Van der Aalst, 2011) occurs by many and diverse rea-

sons, organizational actors perform workarounds at operation time that could be extremely different from the previous prescribed business transaction models. Operation is the collective activity of all the elements within the organization and in the surrounding environment. It encompasses both the productions performed by the elements within the organization and the interactions with the organizational bounds (Dietz, 2006).

Hence, an actor is autonomous in deciding what to do next, and thus misalignments occur between the business transaction models and actor's operation. Moreover, business actors, individually and/or collectively, operate the organization and also administrate and steer it, by means of observing the state of the world and then acting with purpose to change its state. Moreover, an organizational actor is simultaneous a controller agent and a controlled agent within an enterprise. This reason is why steering the operation of business transactions, by the mean of the correct business rules, is strongly needed nowadays on organizations.

As depicted in Figure 1, organizations require steering for continuous verifying if the desired models are satisfied and then to take purposeful actions to correct them. In line, systems control area identifies the need to construct a classic cycle of observation, decision and control to guarantee that the operation of a system satisfies within the desired conditions (Franklin et al., 2009). Accordingly with these principles, Figure 1 enforces an informed decision-making process, which in practice is a steering cycle with the following counterparts: observation (cf. Figure 1(1)), assessing the environment (cf. Figure 1(2)), designing the

Figure 1. Steering cycle: the business transactions are the organizational objects to be controlled, the observed variables are its states and the control variables are the business transactions redesign initiatives

potential solutions (cf. Figure 1(3)) and choosing the best solution (cf. Figure 1(4)). These counterparts recall to the management competences and are mainly human based. Nevertheless, in this paper, we argue and show how automatic tools deliver support to the managers, aiding at some point in their decision-making tasks.

Moreover, organizational steering is most of the time considered as an independent and isolated organizational add-on component that reacts according with the behavior of the part of the organization that is supposed to control (COBIT, 2007). For instance, the General Systems Theory (Bertalanffy, 1969), the Viable System Model (Beer, 1981) and the recent Enterprise Governance proposals (Hoogervorst, 2009; Hoogervorst & Dietz, 2008).

From the literature, organizational steering is related with the ability to control, within a bounded effort, the operation of the enterprise towards a desired prescription whenever changes or perturbations occur. Steering the organizational operation from *a priori* prescribed models derives from the classical control engineering theories. These approaches are still valid for business information systems domain but require contextual adaptation for dealing with holistic concerns such as models change management

Following the proposals of (Guerreiro et al., 2012; Guerreiro & Tribolet, 2013), in these article the authors state that, due to the organizational

complexity, behavior-based approaches are insufficient because it is impracticable to entire specify the dynamics of the system to be controlled without a constructional perspective of the business transaction models. To produce decisions about which action to enact, the understanding of the essential dynamic of the enterprise is crucial.

The proposed solution takes advantage of recent advances in the domain of IS ontology, in specific the Enterprise Engineering (Dietz et al., 2013) and the DEMO theory and methodology (Dietz, 2006), to present a steering solution. It triggers two different control actions whenever a misalignment between the business transactions models and operation are identified: (1) a change in the business transaction models to mitigate the misalignment or (2) a change in the business rules because deviation is considered innovative and thus it should be incorporated in the dynamic of the organization.

BACKGROUND

Classical Dynamic Systems Control

From the perspective of classic control concepts (Franklin et al., 2009) the system that we want to control is the execution of the business transactions. The purpose of a control system is to react whenever the disturbance affects the behavior of

Figure 2. Design pattern of control systems. (A) Without control, (B) feed forward control and (C) feedback control

the system or whenever a new input is established. By other words, when the system is not producing the desired output for the imposed input. Control act in the input at the same time as the disturbance is affecting the system.

Figure 2 depicts classical design patterns for a control system. In the top, (A), it shows a system that is not controlled. The disturbance always affects the output delivered by the system. In this pattern, it is not possible to guarantee the behavior of the system output. In the middle, (B), a feed forward pattern that shows that the system input changes accordingly with the actual disturbance. Therefore, the system dynamics it not included in the control actuation. At the bottom of the Figure 2, (C), a feedback control pattern calculates the system input accordingly with the actual misalignment obtained between the output and input. In this pattern, the control actuation calculation takes into consideration the disturbance and the system dynamics. Because the system output depends on the disturbance imposed in the system and on the system dynamics itself.

Organizational Steering

In reality, many classical dynamic control systems exist within an organization and many different scientific perspectives are actually available to the manager, for instance, General Systems Theory (Bertalanffy, 1969), the Viable System Model (Beer, 1981) and the recent Enterprise

Governance proposals (Hoogervorst, 2009; Hoogervorst & Dietz, 2008). Some examples are the access control models (Ferraiolo et al., 2001) that are responsible to grant or revoke the user's access to the different artifacts that exists in an organization. Other example is the business rules that are responsible to maintain the organizational operation within predefined goals (OMG, 2013). Moreover, in a broader scope, the Enterprise Governance that specifies the design restrictions and the subsequent design for the organizational models (Hoogervorst, 2009). Also, in the IT industrial context, the efforts presented by the well spread ITIL (OGC, 2011), which is a set of good practices to be applied on infrastructures, operation and maintenance of IT services, shows a solution that prescribes and steers the operation and a continuous change management processes. In this line, COBIT (COBIT, 2007) prescribes a framework to enforce IT with control mechanisms, using good practices, policies, procedures, practices and organizational structures. COBIT bridges the gap between business risks, control needs and technical aspects. As the main goal, the undesired events are identified and corrected.

Organizational steering is related with the ability to control, within a bounded effort, the operation of the enterprise towards a desired prescription whenever changes or perturbations occur. In line with this concern, Guerreiro et al. (2012) integrates the DSC concepts with the EE concepts to understand, design and implement the

EDSC. More recently, in (Guerreiro & Tribolet, 2013) the EDSC solution details the control for the actor's activity, checking workarounds between the prescribed models and the observations.

Decision-Making

Decision-making is a management competence (Shewhart, 1980) that encompasses: the intelligence to discover the organizational problems, the design of potential solutions, the choosing of the best solution, the implementation of the solution and the verification if the new solution fulfills the desired goals. These stages occur in many levels of organizational management, *e.g.*, project management, operational management, middle management, etc.

Multiple endogenous and exogenous factors promote the need to enforce a continuous decision-making process, for instance, requirements change, legal changes or fraud attempts. In response to these multiple changes, it is necessary to have native decision-making capabilities that continuously find innovative solutions to adapt the organizational operation to be more efficient and effective. In this context, the study of mechanisms to engineer the informed decision-making (Weber, 1987) are key competence for the success of the organization's management. When combining decision-making with business processes, under complex process-based environments, raise the following challenges *(i)* inability to map the current operational observations with the current state where the organization actually is (Montiel & Bickel, 2012), *e.g.*, when actors perform workarounds (Alter, 2014) and override the previous defined prescriptions then the manager need to collect more information to interpret what, in fact, was executed; and *(ii)* incomplete observations (Cassandra, 1998), *e.g.*, because its too expensive to collect information, or, if the business processes are partially performed in paper by humans and partially machine-based. Therefore, in the majority of the situations, the management should support

their decisions in partial information about the surrounding environment (also named as partial observable environments).

D

The EDSC Related Concepts

The concepts of this section derive from the synthesis of the related literature, with a focus to the core EE concepts (Dietz et al., 2013) and DSC (Franklin et al., 2009).

Transition space and state space: An enterprise is a highly complex system of which large parts, like the state of mind of the people in organization, are fundamentally unknowable. In (Bertalanffy, 1969) two distinct spaces are proposed: state space and transition space. The state space is the set of allowable states of a system. The transition space is the set of allowable sequences of transitions of a system. Moreover, to be conformable with EE concepts, we hold the requirement that every state transition is only dependent on the actual state.

Actors: The actors, human or machine, are part of the enterprise and are organised in a network where the individual and collective views of the enterprise coexist (Dietz et al., 2013). Actors have action freedom and act accordingly with their purposes and orchestrations (Winograd, 1986), organized in social systems. Some portions of the enterprise tasks can be automated by software systems while humans perform others. An actor executes different activities over time. For performing an activity, an actor should fulfill tacitly or explicitly, an actor role. An actor is autonomous in deciding what to do next. An user differs from the actor concept because it represents the corresponding access of a given actor role for a given software system. Typically, a relation between user and actor role exists in the organization.

Business Transaction: A business transaction is the result of applying design constraints for a particular organizational reality, valid over a given period of time, and is useful to share a common understanding between the stakeholders that have a diverse interpretation of it. As proposed in EE

(Dietz, 2006), a business transaction involves (1) actor role definitions, in order to specify who is responsible for each part of the transaction, who initiates it and who executes it, (2) a transition space definition, and (3) a state space definition. The state space is the set of allowable states of a system. The transition space is the set of allowable sequences of transitions of a system. State transitions are not dependent on their previous sequence or on the previous states but only on the actual one. When we refer to run-time business transactions, we are referring to the instances of the business transactions model that are execut-

ing at a precise and single instant in time. Many instances of a business transaction model could be executed at the same time in an organization.

Following the Ψ -theory (Dietz, 2006), two distinct actor roles are identified in the standard pattern of a transaction: the Customer and the Producer. The goal of performing such a transaction pattern is to obtain a new fact. The transactional pattern, depicted in Figure 3, is performed by a sequence of coordination and production acts that produces a new service or product, encompassing three distinct phases: (1) order phase with coordination and production acts of request (rq), promise

Figure 3. The DEMO standard pattern of a transaction between two actors with separation between communication and production acts (Adapted from Dietz, 2006)

(pm), decline (dc) and quit (qt), (2) execution phase that includes production act of execution (ex) of the new fact itself and (3) result phase that includes coordination and production acts of state (st), reject (rj), stop (sp) and accept (ac).

Following this definition of business transaction, we introduce the three fundamental dimensions for a business transaction space. The idea is to incorporate the previous concepts into a unique representation, namely:

- **State Space:** Representing the set of allowable states of a system.
- **Transition Space:** Representing the set of allowable sequences of transitions of a system.
- **Actor Role Space:** Representing the set of allowable competences, authorities and delegations of a system.

Consequently, each state of the business transaction trajectory is defined by a set of triple in the

form: $S = \{ \langle \text{Transition}_i ; \text{State}_i ; \text{ActorRole}_i \rangle, \dots, \langle \text{Transition}_N ; \text{State}_N ; \text{ActorRole}_N \rangle \}$.

The goal of defining a business transaction space, cf. Figure 4, is to limit the expected execution space where an organization should operate its business transactions instances. If, during operation, a trajectory defined within this space is respected then the organizational purposes are fulfilled otherwise the steering functions should be invoked. Therefore, the business processes change decisions are supported by the alignment (or misalignments) from the expected execution space.

Business transaction model and instance: In the scope of business transactions, a difference exists between the model definition and its instances. A model restricts the design freedom and is relevant to share a common understanding between the different stakeholders of an organization (Op't Land et al., 2009). However, they are not sufficient to be operated by the actors. A model implementation is required, and that implementation is instantiated

Figure 4. 3D graphical representation obtained joining transition space, state space and actor roles space of four business transactions. The line represents the expected execution space.

exactly while the actors perform their activities. Moreover, instances are of cornerstone importance in an organization because its existence is revealed while actors perform actions. An actor role is hard defined in the model, but a user is the one that instantiates the model.

Observable/unobservable operation: Is a core concern for controlling any system. To enable control actions, the actor roles, the state space and the transition space modeled in the business transactions models need to be observed during the business transactions instances execution. There are control variables of an enterprise system that are observable, while others are unobservable. Hence, not all the state space and transition space of the enterprise is observable directly in the operation of an enterprise (Franklin et al., 2009). Observation/non-observation is included in our organizational control solution. This concept implies that an organization does not observe everything about the world. Where, the world is the enterprise and the entire surrounding environment. When a control variable is not observable then a fully informed control decision and actuation is not be performed.

Controllable/uncontrollable operation: Two types of control variables exist in a system, those that are controllable and those that are uncontrollable (Franklin et al., 2009). The control action results in changes in the prescribed business transactions models (negative control) or changes in the business rules (positive control). It is a continuously process running in the enterprise. In the negative control, the prescribed business transactions are changed to avoid the recurrence of unintended operations. In the positive control, innovation is recognized as positive and the deviations from the prescribed transactions models are incorporated in the new prescription. In other words, the observed misalignment is valued as being a more innovative way of operating the organization and thus it is used to define a new organizational prescription, in what constitutes in fact continuous organizational learning

Run-time: Instances exist while the actors perform their activities. When an instance is executing, at a single instant in time, it is run-time. When the models are being designed is called design-time. Moreover, the concept of time is always present in the dynamic of the enterprise. Hence, time should also be considered in the enforcement of a solution for controlling the enterprise. The transition space and state space of an instance evolve via events that are produced at run-time.

EDSC: ONTOLOGICAL BUSINESS TRANSACTIONS STEERING

This section details an ontological proposal to enforce the EDSC approach for business transactions when workarounds occur. Resorting the DEMO theory and methodology, a DEMO Organization Construction Diagram (OCD) is presented using the concepts from the previous section. The concepts competences are mapped into a set of ontological transactions and textual described.

Figure 5 presents two feed forward control diagrams that have the previous presented concepts in mind. The top part designs a non-formal specification. The aim is to share the idea of feedback loops in the scope of the organization operation. Informal blocks and arrows depict the control components and information flow. The solution controls the activity of the actors, checking misalignments between the prescribed models and observations. The observed control variables are used to trigger the EDSC. Introducing the metaphor of the Human Central Nervous Systems (CNS) and Peripheral Nervous System (PNS), PNS grounds on the ability to control using a systemic view of the business transactions operations, checking if complies with the ex-ante business transactions and access control models. The result obtained is one control action: (1) a grant or revoke access to the activities that are currently attempted and/or (2) a change to the prescribed models. CNS grounds in the ability

to control using a systemic view of the historical transactions, checking if complies with the ex-ante business rules. The result is one of the following control actions: (1) a change in the business rules, (2) a change in the business transaction model or (3) a change in the access control model. When needed PNS is able to send an order directly to PNS. For instance, new government laws demanding immediate effect.

This solution integration allows the design of a non-singular solution, because any set of business transactions designed in any business domain could benefit from this solution, and not only a particular subset of business domains.

In the bottom of Figure 5 is detailed the OCD for EDSC proposal, using the concepts from the previous section. The goal of an OCD diagram is to design the ontology of a given solution regarding the actors, the production banks, the coordination banks, the boundary and the overall information flow. The proposed concepts in the previous section are enforced by the competences of a set of ontological transactions. The rationale behind these ontological transactions is:

- The prescribed models regarding business rules, business transaction models and actor's access are supported by T01, T02 and T03,
- Managing of business rules, business transactions models and actor's access are supported by T11, T12 and T13,
- The control of current operation, actor's access and business rules are enforced by T05, T06 and T07,
- And the current operation is observed by T04.

Within the EDSC boundary, the goal is to observe the operation and then to act conformal. In detail, the business rule manager (A01) is responsible to self-initiate the business rule definition transaction (T01) and to initiate the business rule management transaction (T11). Similarly, the model manager (A02) is responsible to self-

initiate the model definition transaction (T02) and to initiate the model management transaction (T12). Finally, the access controller (A03) is responsible to self-initiate the access definition transaction (T03) and to initiate the access management transaction (T13). The idea of having a self-initiate transaction is to force the definition of the controller prescriptions. If no references are established then no control act can be performed. In other words, references are considered herein as the control bootstrap. The control actuation in the dynamic of the operation occurs by the instantiation of one of the following transactions: business rule management (T11), model management (T12) or access management (T13).

The observation initiates the observation of run-time session transaction (T04). An actor might be a person or a machine. Ontologically, transaction T04 means the connection of the EDSC kernel with the operation of business transaction instances that are compatible with DEMO standard pattern. In practice, it means that observation is a mandatory requirement to enable EDSC.

Once, the observation over the DEMO business transaction space S is established then control is a matter of evaluating the observations and deciding which the correct action to be taken is. That way, every business transaction instance that we want to control must be connected with the boundary of the EDSC. The idea is that S is operated outside EDSC. EDSC is to be integrated with already existing operating systems.

Finally, the run-time controller executes T05 initiating two parallel transactions: run-time access control (T06), control if the access to the sessions should be granted or revoked, and run-time business rule control (T07), control if the prescribed business rules are satisfied. CPB16 refers to the Period that the EG is being considered, by other words, a period where control is valid, hence an information link exists with EDSC boundary.

Figure 5. EDSC. In the top: using free design figures. In the bottom: the OCD DEMO ontological design.

FUTURE RESEARCH DIRECTIONS

Researching organizational control systems is a paramount venture that drives to manifold applications. In fact, diverse impact areas are identified, *e.g.*, Governance Risk and Compliance, business processes run-time compliance verification and access control (Guerreiro et al., 2011), stochastic solutions for decision-making using Markov theo-

ries (Guerreiro, 2013; 2014; 2015), modeling of enterprises considering the risk factors (Gaaloul & Guerreiro, 2015). Moreover, the following research threads are currently open:

1. **Development of Business Transactions Operation Control Using a Cloud Computing Solution:** Develop a software solution, using cloud computing, that offers

the design, operation and control of real business transactions. The idea is to present to the end users a set of business transactions templates, along with a production platform where the business transactions instances operate (Guerreiro et al., 2013).

2. **Risk Dynamics Combined With Business Transactions:** During the business operation many risks may manifest when comparing the prescribed business transactions with its instances. The manifestation of a risk is a non-conformance behavior during the execution of transactions. Some risks are negative and should be avoided (or even revoked), while others are positive and could be incorporated in an evolvable risk pattern repository. However, when managers get aware about a change in the operational conditions, it is often too late to enforce a change in the business transactions prescriptions. Therefore, a new business process compliance solution, able to evolve along with the real-time occurrence of risks, is needed.
3. **Simulation Environments:** Simulators allow the testing of new strategic governance initiatives, in order to understand, in medium and long terms, which are the impacts of each strategy in the organization. Furthermore, a short-term perspective, simulators help the decision making process at low granularity level, and allow the sharing of a common vision about an organizational operation reality among the different stakeholders (Guerreiro, 2013; 2014; 2015).

CONCLUSION

This article conceptualizes and identifies open research challenges in the scope of informed decision-making applied to business processes execution environments. Control is used to cope the workarounds that occur while actors operate. A workaround occurs when an actor decide to adapt, improvise, or perform other change to one

or more aspects of an existing model. In some situations, a workaround could indicate new, and innovative, ways of actors performing their duties. It is not necessarily harmful for the organization.

The designed solution uses DEMO theory and methodology to elicit the set of purposeful requirements for enforcing control in the operation of run-time business transactions. Three feed forward control loops are identified: (1) the business rules compliance, (2) the access control compliance and (3) the predefined business models compliance. The application of these three feed forward control loops is diverse. The abstraction inherited by ontological solutions delivers a powerful intellectual tool that, in a given instant in time and context, allows to leave some details for further analysis. In this context, our design has allowed the discussion between peers and narrowed the design freedom for the solution. Moreover, this design has been triggering the awareness to enforce control mechanisms (using conceptual and stochastic solutions) in the operational environment of an organization between the peers.

KEY TERMS AND DEFINITIONS

Actor: The actors, human or machine, are part of the enterprise and are organized in a network where the individual and collective views of the enterprise coexist.

Business Transaction: A model representation of a given organizational reality that is valid within a specific timeframe.

Control: The ability to drive, within a bounded effort, the operation of the enterprise towards a desired prescription whenever changes or perturbations occur.

Decision-Making: A management competence that encompasses: the intelligence to discover the organizational problems, the design of potential solutions, the choosing of the best solution, the implementation of the solution and the verification if the new solution fulfills the desired goals.

Observation: The capability to be aware about the internals of the organization and about its surrounding environment.

Operation: The collective activity of all the elements within the organization and in the surrounding environment.

Workaround: How agents with some degree of behavioral discretion decide whether to follow established practices and what to do when exceptions, anomalies and mishaps occur.

Managerial Tools and Techniques for Decision Making

Davood Askarany

University of Auckland, New Zealand

INTRODUCTION

The main aim of this chapter is to explain what considered as managerial tools and techniques for decision making in the area of management accounting and how they developed and evolved over the time. This chapter is intended to help us document the innovation, evolution and the adoption of a variety of relatively new management accounting techniques and practices in organisations. The chapter also looks at primary tasks/services performed by managerial techniques and tools to capture a wider range of techniques/tools that contribute to the conduction of managerial tasks/services but may not be listed as managerial tools in the literature. In doing so, the article first reviews the introduction of management accounting techniques of the past few decades in the literature and then investigates their implementations in practice. Exploring the levels of organizational satisfactions with adopted management accounting innovations in practice, the article finally discusses the level of associations between the adoption of management accounting innovations and organisational satisfaction

BACKGROUND

There is no universal consensus on what techniques constitute management accounting practice and innovations (Cadez & Guilding, 2008). It is argued that many management accounting techniques are drawn from other disciplines such as engineering and economics (Miller, 1998; Miller, Kurunmäki, & O'Leary, 2008). According to

Miller, et al. (2008), practices such as standard costing, discounted cash flow (DCF), break-even analysis, and much more have been drawn from disciplines other than accounting and then adapted, and constituted as the core of accounting. Contributing to our understanding of what techniques constitute management accounting practices and innovations, this chapter reviews the most prevalent management accounting changes introduced in the literature over the past 70 years. It then examines the adoption and diffusion of latest management accounting innovations in organisations. And finally, the chapter discusses the levels of association between organizational satisfactions and adopted management accounting innovations in practice.

MANAGEMENT ACCOUNTING INNOVATIONS

We may refer to relatively new managerial techniques (introduced over the past three decades) as 'innovation' in this chapter. Rogers (2003) defines innovation as an idea, practice, or object that is perceived as new by an individual or another unit of adoption. Further, he suggests that if the individual has no perceived knowledge about an idea and sees it as new, it is an innovation. Likewise, Damanpour and Gopalakrishnan (1998) define innovation as the adoption of an idea or behaviour new to the organisation. The common criterion in any definition of innovation is newness. According to Rogers (2003), newness in an innovation might be expressed not only in terms of new knowledge, but also in terms of

DOI: 10.4018/978-1-5225-2255-3.ch188

the first persuasion, or decision to adopt. Wolfe (1994) explains the diffusion of innovation as a way the new ideas are accepted (or not) by those to whom they are relevant. Rogers (2003) extends this definition to consider diffusion as a process by which an innovation is communicated through certain channels among the members of a social system. In line with above definitions, we may refer to the process of the evolution and the adoption of relatively newer managerial techniques as 'diffusion' in this chapter.

LITERATURE REVIEW

Johnson and Kaplan (1987, p.12) claim that most of current managerial techniques have been developed during the nineteenth century and the first quarter of the twentieth century. They list the most popular techniques and practices developed by 1925 as follows: cost accounts for labour, material, and overhead; budgets for cash, income, and capital; flexible budgets, sales forecasts, standard costs, variance analysis, transfer prices, and divisional performance measures. According to Chandler (1977), management accounting systems (MAS) first appeared in the United States during the nineteenth century. Johnson & Kaplan (1987) reported that before World War I, the Du Pont Company was using almost all of the management accounting procedures for planning and controlling purposes, known until the 1980s. As with the USA, according to Fleischman & Tyson (2006), the use of cost accounting information was first used in a managerial and purposeful fashion in the New England textile industry in the UK during the 1800s. Similar to other countries such as United States, Canada and Great Britain, trade associations in several industries in France were using uniform costing systems from the end of the nineteenth century to the 1940s (Lemarchand, 2002). Bourguignon, Malleret & Nørreklit (2004) report that 'tableau de bord' as a performance measurement technique that focuses on both financial and non-financial

information was used in France during the first half of the twentieth century.

One of important management accounting innovations that was developed in the first half of the 20th century was called Grenzplankostenrechnung (GPK). GPK is a German management accounting technique, developed in the late 1940s and 1950s, proposed to provide reliable and accurate information on products and services' costs. GPK has also been referred to as Marginal Planned Cost Accounting, Flexible Analytic, Cost Planning and Accounting, and Flexible Margin Costing (Friedl, 2005; Sharman, 2003). Georges Perrin method (GPM) is another old management accounting technique created (in French) by Georges Perrin (1891–1958), who believed GPM could meet the emerging needs for cost calculations for the periods after World War Two (Alcouffe, Berland, & Levant, 2008).

However, the growing scope and speed of technological changes and global competitions in 1980s, has resulted in higher demand for more accurate and advanced managerial techniques to provide organisations with more accurate information for the purpose of planning and control decisions (D Askarany & Yazdifar, 2012; D Askarany, Yazdifar, & Askary, 2010; R. S. Kaplan, 1984). That is why Kaplan (1994) suggests that the 1980s and 1990s have seen a revolution in terms of innovations in management accounting theory and procedures. Echoing this observation, Björnenak & Olson (1999) suggest that during the 1980s and 1990s there has been a rich supply of management accounting innovations in the literature.

According to Askarany (2012) and Hagerty (1997)9), the major developments of managerial techniques and practices since the 1950s can be listed as follows:

- **The 1950s:** Discounted cash flows, Total quality management, Cusum charts and Optimum transfer pricing.
- **The 1960s:** Computer technology, Opportunity cost budgeting, Zero-based budgeting, Decision trees, Critical path

scheduling, and Management by objectives. We can refer to computerized or electronic spreadsheets for business accounting as an important tool developed in the 1960s (Mattessich, 1961). However, electronic spreadsheets made their first appearance for personal computers in 1979 in the form of VisiCalc, as an application to help with accounting tasks (Baker & Sugden, 2003, P.1). Fleischman & Tyson (2006) further consider the 1950s and 1960s as the advent of responsibility accounting with an emphasis on cost control via standard costs.

- **The 1970s:** Information economics and agency theory, Just-in-time scheduling, Strategic business units, Experience curves, portfolio management, Materials resource planning, Diversification, Matrix organisation and Product repositioning. VisiCalc Spreadsheet can be considered as an important tool developed in the 1970s (Baker & Sugden, 2003; Power, 2004).

Fleischman and Tyson (2006) argue that Johnson and Kaplan were badly misguided in claiming that nearly most of current management accounting techniques and practices have been developed before 1925. They emphasize that Johnson and Kaplan failed to appreciate the value and the importance of new developments that had occurred after 1925 and before 1970s. Fleischman & Tyson (2006) highlights innovations introduced prior to the 1970 including the development of a number of new mathematical techniques as follows: linear programming for determining profit maximization or cost minimization in the cases of constrained resources; improved methodologies for the investigation of variances; probability analysis under conditions of uncertainty, direct costing, Programming and Budgeting System (PPBS), Program Evaluation and Review Technique (PERT), Zero-Based Budgeting (ZBB).

- **The 1980s:** Activity-based costing (ABC), activity-based management (ABM), Strategic management accounting (SMA), Activity management (AM), Life cycle costing (LCC), Target costing, Value-added management, Theory of constraints, Vertical integration, Private labels, Benchmarking and Supply Chain management (D Askarany, 2014).

Besides above techniques, Lotus 1-2-3, SuperCalc, PlanPerfect, Quattro Pro, VP-PLANNER, AsEasyAs and Excel Spreadsheets can be considered as some of important tools developed in the 1980s (Baker & Sugden, 2003; Power, 2004). Electronic Data Interchange (EDI) and barcoding are important tools that became popular in the 1980s (Premkumar, Ramamurthy, & Nilakanta, 1994). It should be noted that IBM has made a great contribution to the application and diffusion of most of management accounting tools (including the above's) and other computerized and electronic systems such as Enterprise Resource Planning (ERP), Decision Support System (DSS), Material requirements planning (MRP) and Economic Order Quantity (EOQ).

Adding to the above list, Dugdale & Colwyn (1998) include the application of the theory of constraints (TOC) labelled as 'Throughput accounting' as other advanced management techniques developments of 1980s.

- **The 1990s:** Business process reengineering, Quality functional deployment, Balanced scorecard, Outsourcing, Gain-sharing, Core competencies, Time-based competition and Learning organisation and ERP (D Askarany, 2015).

Expanding the above list, we may also include 'Lean accounting' as another development of 1990s (Kennedy & Widener, 2008). The main purpose of Lean accounting is to reduce steps in transaction processing, eliminate standard costs in

favour of actual costs and discontinue cost allocations (Kennedy & Widener, 2008). In describing lean accounting, Kennedy & Widener (2008) refer to Kaizen costing as continuous improvement and reducing time by eliminating waste and reduction of costs that are the main principles of lean accounting. Another management innovation that was introduced in 1990s to deal with overproduction is called 'Lean Manufacturing' (Holweg, 2007; Yang, Hong, & Modi, 2011). According to Yang et al. (2011), lean manufacturing represents a multifaceted concept that may be grouped together as distinct bundles of organizational practices and could include JIT, total quality management, total preventative maintenance, and human resource management, pull, flow, low setup, controlled processes, productive maintenance and involved employees.

Besides above techniques, following managerial techniques may also be considered as further developments of advanced management innovations in the 1990s: Key performance indicators (KPIs), Resource accounting and budgeting (RAB), Functional analysis, Resource management (Lapsley & Wright, 2004) and Resource Consumption Accounting (RCA). RCA has initially emerged as a management accounting approach around 2000 and is largely based on the German management accounting approach Grenzplankostenrechnung (GPK) which also allows for the use of activity-based drivers (Tse & Gong, 2009; White, 2009; Wikipedia, 2013).

- **The 2000s:** Adding to the above developments, we may also consider Time-Driven Activity-Based Costing (TDABC) as further development of advanced management techniques of 2000s (D. Askarany, 2015; D. Askarany & Smith, 2014; R. Kaplan & Anderson, 2007). We can expand the above list by including the Second Generation Balanced Scorecard, the Third Generation Balanced Scorecard and the Performance Prism as further developments of management accounting innovations in the 2000s

((Lawrie & Cobbold, 2004). There is also some discussion on the fourth and fifth generations of balanced score card in recent years (Christesen, 2008).

The above literature review lists a considerable number of management techniques available for practitioners. However, not all of these techniques have received adequate attention by practitioners or even been considered as pure management accounting techniques by some scholars. Reviewing the development of cost and management accounting innovations of past three decades, Askarany (2012) identifies the most popular management accounting techniques addressed in the literature and introduced to practitioners as follows:

- Activity Based Costing (ABC).
- Activity Based Management (ABM).
- Balanced Scorecard (BSC).
- Benchmarking.
- Value chain analysis.
- Total quality management (TQM).
- Strategic management accounting (SMA).
- Target Costing (TC).
- Risk measurement.
- Re-engineering.
- Outsourcing.
- Life cycle costing (LCC).
- Just-in-time (JIT).

Besides above techniques and tools, there are also some approaches and tasks that received considerable attention in recent years and can be viewed through the lenses of managerial tools and techniques such as 'sustainability', 'integrated reporting', 'data mining', and 'customer relationship management'.

We can also look at primary tasks/services performed by managerial techniques and tools and consider to include any technique/tool (not listed above) that contribute to the conduction of these tasks/services as other managerial tools (Spraaakman, O'Grady, Askarany, & Akroyd, 2015). The followings are some examples of

primary tasks/services performed by managerial tools and techniques:

Costing, budgeting, performance measurement, risk assessment, investment evaluation, customer evaluation, profit analysis, rate and volume analysis, business metrics development, revenue and sale forecasting, price modelling, product profitability, industry or client segment reporting, cost analysis, cost–benefit analysis, break-even point analysis, cost-volume-profit analysis, price analysis, life cycle cost analysis, client profitability analysis, capital budgeting, buy vs. lease analysis, make vs. outsource analysis, strategic planning (e.g. Do-View), strategic management advice, internal financial presentation and communication, financial forecasting, annual budgeting, sensitivity analysis, cost allocation and variance analysis.

Many advocates of relatively new managerial techniques suggest that the adoption of these techniques could contribute to the overall performance of organisations and increase organisational satisfaction (Tatsiopoulos & Panayiotou, 2000; Thyssen, Israelsen, & Jørgensen, 2006; Tornberg, Jämsen, & Paranko, 2002). For example, Maiga & Jacobsred (2008) find that the extent of ABC implementation in organisations is significantly and positively associated with quality, cost, profitability and cycle-time improvements. As another example, Banker & Mashruwala (2007) and Vera-Muñoz et al. (2007) find a significantly positive correlation between employee satisfaction and improved profitability (due to the adoption of managerial technique) in organisations. However, it is not very clear how these techniques have been prevailed in practice. It is also not very clear whether (or not) organisations are satisfied with the performance of their implemented managerial techniques and whether (or not) there is a link between organisational satisfaction and the diffusion of managerial techniques in practice. These questions are addressed in the following section.

DIFFUSION OF MANAGEMENT ACCOUNTING INNOVATIONS IN PRACTICE

Examining the extent of implementation of management accounting innovations in practice, Askarany (2012) finds the adoption rates for some of popular management accounting innovations in Australia as follows: ABC 19%, ABM 11%, BSC 23%, Benchmarking 35%, SMA 13% and TC 15%.

In another study Yazdifar & Askarany (2009) report the adoption rates for the above management accounting innovations in New Zealand and the UK as follows:

- **New Zealand:** ABC 22.5%, ABM 16.9%, BSC 21.4%, Benchmarking 35.2%, SMA 28.2% and TC 18.3%.
- **UK:** ABC 15.2%, ABM 15.2%, BSC 31.8%, Benchmarking 34.8%, SMA 15.2% and TC 16.7%.

Askarany (2012) further explores the level of organizational satisfactions with their implemented management accounting techniques in Australia to see if the adoption of management accounting innovations has contributed to organizational satisfaction. He reports the level of satisfaction of Australian firms with their implemented cost and management accounting systems as follows: Very dissatisfied 7%, Dissatisfied 13%, Moderately satisfied 32% and Very satisfied 9%.

Furthermore, Askarany's (2012) study finds no significance association between organizational satisfaction and the levels of implementation of any of above management accounting innovations in practice. Thus, his findings do not support the notion that the higher the levels of adoption of management accounting innovations, the higher the levels of organizational satisfaction. Though the above findings are not in line with what advocates of management accounting innovations (e.g. Maiga & Jacobs, 2008) believe, the results

are consistent with those findings (e.g. Banker, Bardhan, & Chen, 2008) which suggested that the adoption of management accounting innovation by itself does not improve organizational performance. Given that the majority of these so called management accounting innovations was introduced more than 10-20 years ago, finding no significance association between organizational satisfaction and the levels of implementation of these management accounting innovations could also imply that these techniques have lost their relevance to cope with the new requirements of current organisations.

SOLUTIONS AND RECOMMENDATIONS

These results represent research views situation in Australia, New Zealand and the United Kingdom. However, the experience of other countries, especially of the USA that is a leader in this field and also European developed countries, could vary significantly. For instance, Comparing U.S. and German Cost Accounting Methods, Krumwiede & Suessmair (2007) find a significant difference between U.S. and German organisations (both manufacturing and non-manufacturing organisations) in terms the level of satisfaction with their adopted cost and management accounting systems. Their findings show that German firms have rated their overall satisfactions with their adopted management accounting techniques as 77% (for non-manufacturing firms) to 78% (for manufacturing firms) compared to 23% (for manufacturing firms) to 26% (for non-manufacturing firms) for U.S. firms.

FUTURE RESEARCH DIRECTIONS

Reporting relatively low adoption rates for management accounting innovations as well as low level of organisational satisfaction with the

performance of such innovations suggest further studies into the appropriateness and capability of recent management accounting innovations. In other words, the perceived advantages of management accounting innovations may be inadequate to pursue their adoptions in practice. Or, similar to traditional management techniques, management accounting innovations may have some shortcomings that could prevent them to improve organisational satisfactions.

Despite the introduction and use of majority of management accounting innovations described in this chapter, many organisations worldwide have gone through receivership or collapsed due to either inadequate attention to risk management, performance measurement, overproduction, environment, and stakeholders' needs and preferences or dealing with them in isolation (not altogether and not at the same time). So, it seems to be a need for a dynamic integrated management accounting innovation to simultaneously pay attention to several important factors such as performance management and risk management, overproduction, environment, society and stakeholders' need and preferences.

Inadequate attention to risk management, performance measurement, overproduction, environment, and stakeholders' needs and preferences or dealing with them in isolation are among the problems of the future and could lead to economic crises and obstruction for balanced economic development. So, it is necessary to improve management and management accounting techniques as management accounting should be an amortization means for economic crises. Logistic analysis and overproduction management theory, for instance, could be used in management process for the elimination of potential overproduction. As another example, risk factors, environment and stakeholders' needs and preferences, could be added to balanced scorecard perspectives to simultaneously pay attention to all key performance and key risk indicators in organisations.

CONCLUSION

The purpose of this chapter is to get a clear picture of the scope and extent of recently developed cost and management accounting innovations in the literature as well as their implementation in practice. The chapter identifies the most popular management accounting innovations of past several decades in the literature and reports on the latest adoption rates of most recent management accounting innovations as well as their associations with organisational satisfactions in some selected countries.

The current chapter identifies some popular cost and management accounting changes/innovations of past three decades as follows: performance measurement and BSC techniques, ABC, TDABC, valued added concepts, ABM, TQM, strategic management, risk management, benchmarking, re-engineering, and target costing. However, from the implementation perspective, the chapter suggests that recent management accounting innovations are not widely implemented in practice.

Reviewing the level of association between organizational satisfaction and the adoption of management accounting innovations, the chapter further reports no significant association between organizational satisfaction and the implementation of any of above management accounting innovations. Considering the cost and benefit philosophy, this chapter suggests that perceived advantages of these relatively new management accounting innovations could be inadequate to pursue their adoptions in practice.

This chapter provides a historical review on the evolution and the diffusion of a variety of relatively new management accounting techniques and practices in organisations in general. However, in terms of the level of organisational satisfaction with adopted management accounting innovations, the results are mainly from studies carried out in limited countries: Australia, New Zealand and the United Kingdom and to some extent the USA and Germany. The findings show that the level

of satisfaction with management accounting innovations varies significantly across the countries. Further studies are recommended to explore the experiences of other countries with the adoption of management accounting techniques in practice.

KEY TERMS AND DEFINITIONS

Activity-Based Costing (ABC): An approach to costing that focuses on activities as the fundamental cost objects. It uses the cost of these activities as the basis for assigning costs to other cost objects such as products, services, or customers.

Activity-Based Management (ABM): Use of ABC concepts to facilitate the identification and reduction of non-value-added activities.

Balanced Scorecard: An integrated strategic performance management framework that helps organisations translate strategic objectives into relevant performance measures, by linking non-financial measures with a financial perspective in four areas of performance concerned with: financials, internal process, customers and innovation & learning.

Benchmarking: The search for industry best practice that will lead to superior performance. It emphasises an outward focus and seeks to improve performance by learning from the experience of effective organisations.

Life Cycle Costing: A costing method that tracks and accumulates the actual costs attribut-

able to each product from its initial research and development to its final customer servicing and support in the marketplace.

Strategic Management Accounting (SMA):

A focus on the analysis of the external environment which mandates corrections and adjustments to the internal control systems structures and decision support systems that are vital for the survival of organisations. SMA has an orientation towards

the organisation's environment such as suppliers, customers, and its competitive position relative to both existing and potential competitors.

Target Costing: A form of costing system in which the manufacturing of a product or the provision of a service is restricted within a pre-determined total cost ceiling so that a competitive price is achieved.

D

A Nature-Inspired Metaheuristic Approach for Generating Alternatives

Julian Scott Yeomans
York University, Canada

INTRODUCTION

Decision-making in the “real world” involves complex problems that tend to be riddled with competing performance objectives and possess requirements which are very difficult to incorporate into any underlying decision support models (Brugnach, Tagg, Keil, De Lange, 2007; Janssen, Krol, Schielen, Hoekstra, 2010; Mowrer, 2000; Walker, Harremoes, Rotmans, Van der Sluis, Van Asselt, Janssen, Krayen von Krauss, 2003). While an optimal solution might provide the theoretically best answer to a mathematical model, in general, it will not be the best solution to the fundamental “real” problem since there are invariably unmodelled objectives and unquantifiable issues not incorporated in the problem formulation (Brugnach *et al.*, 2007; Gunalay, Yeomans, 2012; Gunalay, Yeomans, Huang, 2012; Janssen *et al.*, 2010; Loughlin, Ranjithan, Brill, Baugh, 2001). Consequently, it is preferable to generate a number of different alternatives that provide multiple, disparate perspectives to any particular problem (Imanirad, Yeomans, 2014; Matthies, Giupponi, Ostendorf, 2007; Yeomans, Gunalay, 2011). Preferably these alternatives should all possess good (i.e. near-optimal) objective measures with respect to the modelled objective(s), but be as fundamentally different as possible from each other in terms of the system structures characterized by their decision variables (Yeomans, 2011).

To address this option creation need, several approaches collectively referred to as *modelling-to-generate-alternatives* (MGA) have been developed (Loughlin *et al.*, 2001; Yeomans, Gunalay, 2011; Yeomans, 2012). The principal motivation

for MGA is to create a small set of alternatives that are as maximally different from each other in the decision space as possible, yet are still considered “good” with respect to all of the modelled objective(s) (Yeomans, 2011; Yeomans, 2012). By adopting a maximally different method, the resulting alternative solution set is likely to provide very different perspectives with respect to any unmodelled issues, while simultaneously providing different choices that all perform somewhat similarly with respect to the modelled objectives (Gunalay, Yeomans, 2012; Gunalay *et al.*, 2012; Walker *et al.*, 2003; Yeomans, 2011).

In this chapter, it is shown how a modified version of the metaheuristic Firefly Algorithm (FA) of Yang (2009; 2010) can be used to efficiently generate a set of maximally different solution alternatives. Yang (2010) has demonstrated that, for optimization and calculational purposes, the FA is more computationally efficient than the more commonly-employed enhanced particle swarm, genetic algorithm, and simulated annealing metaheuristic procedures. Thus, this FA-based MGA procedure can be considered very computationally efficient (Imanirad, Yeomans, 2014). This demonstrates the MGA proficiencies of the FA-based approach for constructing multiple, maximally different solution alternatives to the highly non-linear optimization problem of Loughlin *et al.* (2001).

BACKGROUND

While this section provides a brief synopsis of the steps involved in the FA process, more specific details can be found in Yang (2009; 2010). The

Algorithm 1.

```

Objective Function  $F(\mathbf{X})$ ,  $\mathbf{X} = (x_1, x_2, \dots, x_d)$ 
Generate the initial population of  $n$  fireflies,  $\mathbf{X}_i$ ,  $i = 1, 2, \dots, n$ 
Light intensity  $I_i$  at  $\mathbf{X}_i$  is determined by  $F(\mathbf{X}_i)$ 
Define the light absorption coefficient  $\gamma$ 
while ( $t < \text{MaxGeneration}$ )
    for  $i = 1: n$ , all  $n$  fireflies
        for  $j = 1: n$ , all  $n$  fireflies (inner loop)
            if ( $I_i < I_j$ ), Move firefly  $i$  towards  $j$ ; end if
            Vary attractiveness with distance  $r$  via  $e^{-\gamma r^2}$ 
        end for  $j$ 
    end for  $i$ 
    Rank the fireflies and find the current global best solution  $\mathbf{G}^*$ 
end while
Postprocess the results

```

FA is a nature-inspired, population-based meta-heuristic that employs the following three idealized rules: (i) All fireflies within a population are unisex, so that one firefly will be attracted to other fireflies irrespective of their sex; (ii) Attractiveness between fireflies is proportional to their brightness, implying that for any two flashing fireflies, the less bright one will move towards the brighter one. Attractiveness and brightness both decrease as the distance between fireflies increases. If there is no brighter firefly within its visible vicinity, then a particular firefly will move randomly; and (iii) The brightness of a firefly is determined by the landscape of the objective function. Namely, for a maximization problem, the brightness can simply be considered proportional to the value of the objective function. Based upon these three rules, the basic operational steps of the FA are summarized within the pseudo-code of Algorithm 1 Yang (2010).

In the FA, there are two important issues to resolve: the variation of light intensity and the formulation of attractiveness. For simplicity, it can always be assumed that the attractiveness of a firefly is determined by its brightness which in turn is associated with the encoded objective function. In the simplest case, the brightness of a firefly at a particular location $\mathbf{X}$ would be its

calculated objective value $F(\mathbf{X})$. However, the attractiveness, β , between fireflies is relative and will vary with the distance r_{ij} between firefly i and firefly j . In addition, light intensity decreases with the distance from its source, and light is also absorbed in the media, so the attractiveness should be allowed to vary with the degree of absorption. Consequently, the overall attractiveness of a firefly can be defined as

$$\beta = \beta_0 \exp(-\gamma r^2)$$

where β_0 is the attractiveness at distance $r = 0$ and γ is the fixed light absorption coefficient for a specific medium. If the distance r_{ij} between any two fireflies i and j located at $\mathbf{X}_i$ and $\mathbf{X}_j$, respectively, is calculated using the Euclidean norm, then the movement of a firefly i that is attracted to another more attractive (i.e. brighter) firefly j is determined by

$$\mathbf{X}_i = \mathbf{X}_i + \beta_0 \exp(-\gamma(r_{ij})^2)(\mathbf{X}_i - \mathbf{X}_j) + \alpha \mathbf{e}_i.$$

In this expression of movement, the second term is due to the relative attraction and the third term is a randomization component. Yang (2010) indicates that the randomization parameter, α , is normally selected within the range $[0,1]$ and $\mathbf{e}_i$ is

a vector of random numbers drawn from either a Gaussian or uniform (generally $[-0.5, 0.5]$) distribution. It should be noted that this expression is a random walk biased toward brighter fireflies and if $\beta_0 = 0$, it becomes a simple random walk. The parameter γ characterizes the variation of the attractiveness and its value determines the speed of the algorithm's convergence. For most applications, γ is typically set between 0.1 to 10 (Yang, 2010). In any given optimization problem, for a very large number of fireflies $n \gg k$ where k is the number of local optima, the initial locations of the n fireflies should be distributed relatively uniformly throughout the entire search space. As the FA proceeds, the fireflies would converge into all of these local optima (including the global ones). By comparing the best solutions among all these optima, the global optima can easily be determined. Yang (2010) demonstrates that the FA will approach the global optima when $n \rightarrow \infty$ and the number of iterations t , is set so that $t \gg 1$. In reality, the FA has been found to converge extremely quickly.

Two important limiting or asymptotic cases occur when $\gamma \rightarrow 0$ and when $\gamma \rightarrow \infty$. For $\gamma \rightarrow 0$, the attractiveness is constant $\beta = \beta_0$, which is equivalent to having a light intensity that does not decrease. Thus, a firefly would be visible anywhere within the solution domain. Hence, a single (usually global) optima can easily be reached. If the inner loop for j in Figure 1 is removed and X_j is replaced by the current global best G^* , then this implies that the FA becomes a special case of the accelerated particle swarm optimization (PSO) algorithm. Subsequently, the computational efficiency of this special case of the FA is equivalent to that of enhanced PSO. Conversely, when $\gamma \rightarrow \infty$, the attractiveness is essentially zero in the sightline of other fireflies. This is equivalent to the case where the fireflies randomly roam throughout a very thick foggy region. No other fireflies are visible and each firefly roams in a completely random fashion. This case corresponds to a completely random search method.

As the FA operates between these two extremes, it is possible to adjust the parameters α and γ so that the FA can outperform both the random search and the enhanced PSO algorithms. Furthermore, the FA can find both the global optima as well as the local optima concurrently which holds computational and efficiency advantages for MGA purposes (Yeomans, Gunalay, 2011). Another additional advantage of the FA for MGA implementation is that different fireflies essentially work independently of each other and FA are thus better than genetic algorithms and PSO for MGA because the fireflies can aggregate more closely around each local optimum.

MAIN FOCUS OF THE ARTICLE

Most mathematical programming algorithms originating in planning research literature have focused almost entirely on producing optimal solutions for single-objective formulations or, equivalently, generating noninferior solution sets for multi-objective problems (Loughlin *et al.*, 2001; Zechman, Ranjithan, 2004). While such methods may efficiently generate solutions to the derived mathematical models, whether their results actually establish “best” approaches to the underlying “real” problems is debatable.

In most “real world” decision-making, there are numerous system requirements and objectives that are never incorporated into the modeling, or even apparent, when the problems are being initially formulated (Brugnach *et al.*, 2007; Walker *et al.*, 2003). Furthermore, it may never be possible to explicitly convey all of the subjective considerations because there are frequently numerous competing, adversarial, incompatible stakeholder groups. Therefore most subjective aspects remain unquantified and unmodelled in the construction of any corresponding decision models. This is a common occurrence in situations where the final decisions are constructed based not only upon clearly stated and modelled objectives, but also

upon fundamentally subjective, socio-economic and political goals and stakeholder preferences (Yeomans, Gunalay, 2011). Numerous “real world” examples of this type of incongruent modelling duality are described in the literature (Baugh, Caldwell, Brill, 1997; Brill, Chang, Hopkins, 1982; Loughlin *et al.*, 2001; Zechman, Ranjithan, 2004).

Modelling to Generate Maximally Different Alternatives

When unmodelled objectives and unquantified issues exist, different approaches are required in order to not only search the decision space for the noninferior set of solutions, but also to explore the decision space for *inferior* alternative solutions to the modelled problem. In particular, any search for good alternatives to problems known (or suspected) to contain unmodelled objectives must focus not only on the non-inferior solution set, but also necessarily on an exploration of the problem’s inferior region.

To illustrate the implications of an unmodelled objective on a decision search, assume that the optimal solution for a quantified, single-objective, maximization decision problem is X^* with corresponding objective value ZI^* . Now suppose that there exists a second, unmodelled, maximization objective $Z2$ that perhaps subjectively reflects environmental/political acceptability. Let the solution X^a , belonging to the noninferior, 2-objective set, represent a potential best compromise solution if both objectives could somehow have been simultaneously evaluated by the decision-maker. While X^a might be viewed as the best compromise solution to the real problem, it would clearly appear inferior to the solution X^* in the quantified model, since it must be the case that $ZI^a \leq ZI^*$.

This observation implies that when unmodelled objectives are factored into the decision making process, mathematically inferior solutions for modelled problems can potentially be optimal for the real problems. Therefore, when unmodelled objectives and unquantified issues might exist,

different approaches are required in order to not only search the decision space for the noninferior set of solutions, but also to simultaneously explore the decision space for inferior alternative solutions to the modelled problem. Population-based procedures such as the **FA** permit concurrent searches throughout a feasible region and thus prove to be particularly adept methods for searching through a problem’s decision space.

The primary motivation behind MGA is to produce a manageably small set of alternatives that are quantifiably good with respect to known modelled objective(s) yet are **maximally different** from each other within the decision space. In so doing, the resulting solution set is likely to provide truly different alternatives that all perform somewhat similarly with respect to the modelled objective(s) yet very differently with respect to any unmodelled issues. By generating these maximally different solutions, the decision-makers can explore alternatives that may satisfy the unmodelled objectives to varying degrees of stakeholder acceptability. Obviously the solution-setters must then conduct a subsequent comprehensive comparison of the alternatives to determine which options would most closely satisfy their very specific circumstances. Thus, an **MGA** approach should necessarily be considered as one of decision support rather than of explicit solution determination.

In order to properly motivate an **MGA** search procedure, it is necessary to provide a more formal definition of the goals of maximal difference in the MGA process (Loughlin *et al.*, 2001; Yeomans, Gunalay, 2011). Suppose the optimal solution to an original mathematical model is X^* with objective value $Z^* = F(X^*)$. Then the following maximal difference model can be solved to determine an alternative solution that is **maximally different** from X^* :

$$\text{Max } \Delta = \sum_i |X_i - X_i^*|$$

Subject to: $X \in D$

$$|F(X) - Z^*| \leq T$$

where Δ is a difference function (shown as a simple absolute difference in this instance), D is the original mathematical model's feasible domain and T is a target deviation specified in relation to the original optimal function value Z^* . T is a user-supplied value that represents how much of the inferior region is to be explored for alternative solutions.

The FA-based MGA procedure is designed to generate a small number of maximally different alternatives by iteratively adjusting the value of T and using the FA to solve the corresponding, new maximal difference problem instance. Each desired solution alternative undergoes the common search procedure of the FA. The survival of solutions depends upon how different they are from all of the other previously generated alternatives in the decision space and by how well the solutions perform with respect to the modelled objective(s).

Computational Testing of the Firefly Algorithm Used For MGA

As described above, planners generally prefer to be able to select from a set of “near-optimal” alternatives that differ significantly from each

other in terms of the system structures characterized by their decision variables. In order to create this set of alternative planning options, extra target constraints that varied the value of T were placed into the original model formulation in order to force the generation of solutions that were maximally different from the initial optimal solution. The application of this MGA solution creation approach will be demonstrated using a 100-peak multimodal optimization problem taken from Loughlin *et al.* (2001).

The mathematical formulation for the multimodal test problem of Loughlin *et al.* (2001) is:

$$\begin{aligned} \text{Maximize } F(x, y) &= \sin(19\pi x) + \frac{x}{1.7} + \sin(19\pi y) \\ &+ \frac{y}{1.7} + 2 \\ 0.0 &\leq x \leq 1.0 \end{aligned}$$

$$0.0 \leq y \leq 1.0$$

The feasible region corresponding to this problem contains 100 peaks separated by valleys with the increasing amplitudes for both the peaks and valleys as the values of the decision variables

Table 1. Objective values and solutions for the 11 maximally different alternatives

Increment	1% Increment Between Alternatives			2.5% Increment Between Alternatives		
	$F(x,y)$	x	y	$F(x,y)$	x	y
Optimal	5.14	0.97	0.97	5.14	0.97	0.97
Alternative 1	5.10	0.98	0.97	5.01	0.87	0.87
Alternative 2	5.05	0.87	0.98	4.89	0.66	0.87
Alternative 3	5.00	0.76	0.98	4.77	0.87	0.45
Alternative 4	4.99	0.98	0.87	4.65	0.33	0.97
Alternative 5	4.91	0.98	0.76	4.50	0.98	0.02
Alternative 6	4.89	0.55	0.97	4.43	0.02	0.98
Alternative 7	4.89	0.98	0.55	4.29	0.98	0.02
Alternative 8	4.74	0.34	0.98	4.13	0.02	0.99
Alternative 9	4.69	0.98	0.24	4.02	0.99	0.02
Alternative 10	4.64	0.13	0.98	3.87	0.01	0.98

increase from their lower bounds of (0,0) toward their upper limits at (1,1). For the design parameters employed in this specific problem formulation, the mathematically optimal solution of $F(x, y) = 5.146$ occurs at point $(x, y) = (0.974, 0.974)$ (Loughlin *et al.*, 2001). The incremental MGA difference approach outlined in the previous section was used to produce the optimal solution and the 10 maximally different solutions shown in Table 1.

As outlined earlier, many “real world” problem applications tend to be riddled with incongruent performance requirements that are very difficult to quantify. Consequently, it is preferable to create several quantifiably good alternatives that concurrently provide very different perspectives to the potentially unquantifiable and unmodelled performance design issues during the policy formulation stage. The unique performance features captured within these dissimilar alternatives can result in very different system performance with respect to the unmodelled issues, thereby incorporating the unmodelled issues into the actual solution process. These two examples have demonstrated how an MGA modelling perspective can be used to generate multiple, good alternatives via the very computationally efficient FA that satisfy required system performance criteria according to prespecified bounds and yet remain as maximally different from each other as possible in the decision space. In addition to its alternative generating capabilities, the MGA procedure has simultaneously performed exceedingly well with respect to its role in function optimization. It should be explicitly noted that the overall best solution produced by the MGA procedure for the test problem is indistinguishable from the one determined in Loughlin *et al.* (2001).

FUTURE RESEARCH DIRECTIONS

In this chapter, an algorithm was presented that illustrated how the computationally efficient FA could be employed to generate numerous,

maximally different, near-best solutions. In this MGA role, the FA produces multiple alternatives possessing the required problem features, with each generated solution providing a different perspective. Since FA techniques have been applied to a wide spectrum of problem types, the practicality of this MGA approach can clearly be extended into numerous different planning environments. One such area of application would be to problems which contain significant degrees of stochastic uncertainty. Stochastic MGA approaches have only recently been considered within the research literature (Imanirad, Yang, Yeomans, 2016; Yeomans, Imanirad, Yang, 2014). Furthermore, although the FA provides one highly-efficient, computational procedure, there are numerous other nature-inspired metaheuristics that could be similarly employed. The computational efficacy of these extensions will provide the foundation for numerous future research studies.

CONCLUSION

Decision-making in the “real world” can be very complicated and frequently influenced by numerous unquantifiable issues, unmodelled objectives and uncertain factors. These uncertain and competing components oblige the decision-makers to assimilate several incompatible elements into the solution process prior to determining a final decision resolution. With so much uncertainty, it is doubtful that any single solution could ever be constructed that concurrently fulfills all of the incongruent system requirements. Thus, any ancillary modelling that supports the decision process needs to simultaneously consider all of these features while being malleable enough to capture the influences of any inherent planning uncertainty. FA-based MGA supplies an appropriate computational approach to support such “real world” decision-making applications.

KEY TERMS AND DEFINITIONS

Firefly Algorithm: The Firefly Algorithm is a computationally efficient, nature-inspired, population-based metaheuristic that derives its solution approach based upon the characteristics of fireflies.

Heuristics: Approximation schemes used in problem-solving to generate good, though not necessarily optimal, solutions to mathematical programming problems.

Maximally Different Solutions: “Good” solution alternatives should possess near-optimal objective measures with respect to all of the known modelled objectives, but be fundamentally different from each other in terms of the system structures characterized by their decision variables. A difference model is employed to generate alternatives that are as far apart in the decision space as possible. The resulting alternative solution set of MGA provides disparate choices that all

perform well with respect to the known modelled objectives, yet very differently with respect to any unknown, unmodelled and/or unquantified issues. Hence, these solutions will provide entirely different perspectives to the original problem.

Meta-Heuristics: High-level, overarching heuristic approaches that have wide-ranging applicability to many different mathematical programming problems.

Modelling to Generate Alternatives (MGA): A modelling approach to systematically provide a set of “good” alternatives with respect to all of the problem’s modelled objectives. The primary motivation for MGA is to produce a manageably small set of alternatives that are good with respect to the known modelled objectives yet as different as possible from each other in the decision space – namely the solution set should provide maximally different alternatives.

Nature-Inspired Meta-Heuristics: Meta-heuristics whose fundamental solution characteristics have been motivated by phenomena occurring in the natural environment.

Stochastic MGA: Modelling to Generate Alternatives in which some or all of the parameters, objectives, constraints and/or other problem characteristics are expressed in some form of uncertainties, probability distributions or some other stochastic representation.

Unmodelled Issues: Aspects of a mathematical problem not captured during the construction and formulation of its corresponding mathematical/computer model.

Unquantified Issues: System objectives and requirements that are neither explicitly apparent nor included in the problem formulation stage—it is impossible to express these aspects quantitatively.

Preferences, Utility, and Stochastic Approximation

INTRODUCTION

A complex system with human participation like “human-process” is characterized with active assistance of the human in the determination of its objective and description, and in decision-taking during its development. The construction of a mathematically grounded model of such a system is faced with the problem of shortage of mathematical precise information that presents the human activity. Often, in complex processes there is a lack of measurements or even clear scales for the basic heuristic information. On this level of investigations the decisions is close to the art to choose the right decision among great number of circumstances and often without associative examples of similar activity. The basic common source of information here are the expressed human preferences. A solution of this problem is to seek interpretation and expression of different aspects of the complex system through expert analysis and description of the expert’s preferences as an element of the system.

The presentation of human preferences analytically with utility functions is a good possible approach for their mathematical description. It is the first step in realization of a human-centered value driven design process and decision making, whose objective is to avoid the contradictions in human decisions and to permit mathematical calculations. In this approach the human being has the role of decision maker (DM). If the subjective and probability uncertainty of DM preferences is

interpreted as some stochastic noise, stochastic programming can be used for recurrent evaluation of the utility function in the sense of von Neumann with noise (uncertainty) elimination. In fact this is pattern recognition of the positive and negative DM’s answers in regarding to his preferences expressed as comparisons between lotteries in the gambling approach. The utility evaluation is human-computer dialog between a decision maker and computer-based evaluation tool. It concerns mathematically machine learning, since its basis is the axiomatic approach to decision making theory and stochastic approximation. The latter presents unique stochastic recurrent procedures suitable for computer programming.

The American psychologists Griffiths and Tenenbaum (2006) by analyzing intuitive evaluations in the conditions of repetitive life situations have proved the statistical optimality of human assessment. The major idea is that the new data is interpreted in the framework of a probability model built in their consciousness. That means that the Bayesian approach is a natural basis on which human beings formed their decisions, using their previous empirical experience. In such case the *utility theory* and its prescription to make decision based on value (utility) model as mathematical representation of the preferences has another scientific validation of the axiomatic approach in *decision making*. This modeling and its implementation in design is one of the directions of *value driven design*. The latter is a system engineering strategy, which enables multidisciplinary

design optimization by providing designers with an objective function.

People's preferences contain uncertainty of probabilistic nature due to qualitative type both of the empirical expert information and human notions. A possible approach for solution of these problems is *stochastic programming* (Aizerman et al., 1970). The uncertainty of the subjective preferences could be taken as an additive noise that could be eliminated, as is typical in the stochastic approximation procedures and *machine-learning* based on the stochastic programming.

The objective of the article is to present an innovative approach to value driven modeling of management (control) that bases on preference-oriented decision making. It is described a decision technology that realizes measurement (value-based evaluation) of human's objective-oriented preferences as analytic utility function. The latter is used in human-centered modeling of management/control that bases on the value-oriented determination of requirements and preferences of a human being in representation of complex processes. The utility theory and stochastic approximation are possible solution of this problem that results in a value-based approach to modeling of complex systems. It is demonstrated the application of the described value driven approach to management modeling in design of portfolio optimal control.

BACKGROUND

In complex processes and situations, there is a lack of measurements or even clearly identifiable scales for the basic heuristic information. Internal human expectations and heuristic are generally expressed by qualitative preferences. That is why the common sources of information in such a basic level are the human preferences. Probability theory, stochastic programming and expected utility theory address decision making under these conditions (von Neumann & Morgenstern, 1953; Raiffa, 1968; Pfanzagl, 1970; Fishburn, 1970). The mathematical description on such a fundamental

level requires basic mathematical terms like sets, relations and operations over them. In this aspect of mathematical descriptions it is entered the theory of measurements and scaling and utility theory.

From practical point of view the empirical system of human preferences relations is an algebraic system with relations. *System with relations* (SR) is called the set A in conjunction with a set of relations $R_i, i \in I, I = \{1, 2, 3, \dots, n\}$ defined over it and denoted by $(A, (R_i), i \in I)$. In this manner it is introduced a structure in the set A (Pfanzagl, 1970). Relation of *congruency* is called a relation of equivalency ($\approx$) (reflexive, symmetric and transitive) defined over the basic set A , if the property of *substitution* is satisfied, i.e. from the fulfillment of relations $(x_1, x_2, x_3, \dots, x_{hi}) \in A^{hi}$ and $(x_j \approx y_j)$ for every $j=1, 2, 3, 4, \dots, h_i$ it follows that $R_i(x_1, x_2, x_3, \dots, x_{hi}) = R_i(y_1, y_2, y_3, \dots, y_{hi})$ for $\forall i, i \in I$. By definition the relation of equivalency ($\approx_1$) is coarser than the equivalency ($\approx_2$), if the inclusion $(\approx_1) \subseteq (\approx_2)$ is satisfied. It is known that there exists the coarsest relation ($\approx_A$) over SR $(A, (R_i), i \in I)$. This means that if two elements are in congruency relation $(x \approx_A y)$, then they are undistinguishable, with respect to the properties, in the set A , described with the set of relations $((R_i), i \in I)$. If the set A is factorized by the coarsest congruency ($\approx_A$), then in the factor set $A/\approx_A$ the congruency ($\approx_A$) is in fact equality ($=$). A SR $(A, (R_i), i \in I)$, in which the congruency ($\approx_A$) is the coarsest is called *irreducible*. In this case SR $(A/\approx_A, (R_i), i \in I)$ is irreducible.

A homomorphism is an image $f, f: A \rightarrow B$ between two SR $(A, (R_i), i \in I)$ and $(B, (S_i), i \in I)$ from the same type, for which $\forall i, i \in I$ and $(x_1, x_2, x_3, \dots, x_{hi}) \in R_i$ is satisfied $R_i(x_1, x_2, x_3, \dots, x_{hi}) \Leftrightarrow S_i(f(x_1), f(x_2), f(x_3), \dots, f(x_{hi}))$.

DEFINITION: Every homomorphism from irreducible empirical system into the number system SR $(A, (Q_i), i \in I)$ is called k -dimensional scale.

The empirical system of relations SR is an object from the reality with the properties described by the relations in SR, while the numbered system

of relations SR is a mathematical object which reflects the interesting properties in the real object.

In the definition for the scale the correspondence $f_\theta: A \rightarrow R^k$ is not simply defined (R^k is the k -ary Cartesian product of the set of the real numbers). In general sense, there exists entire class of scales converting the irreducible empirical system of relations SR $(A, (R_i), i \in I)$ into the number system SR $(R^k, (S_i), i \in I)$. This class of homomorphism (scales) is denoted by $\mathfrak{N}(A, R^k)$ (every homomorphism is injective in its essence, because the empirical system is irreducible and surjective with regard to $f(A)$). Let A_0 be a subset of A . We denote by $G_A(A_0)$ all injective homomorphism, inclusion (*partial endomorphism*) from SR $(A_0, (R_i), i \in I)$ in SR $(A, (R_i), i \in I)$. If a scale $f_\theta \in \mathfrak{N}(A, R^k)$ is given, then we can characterize the whole class of scales $\mathfrak{N}(A, R^k)$ in the following way: $\mathfrak{N}(A, R^k) = \{\gamma \circ f_\theta / \text{where } \gamma \in G_R^k(f_\theta(A))\}$. Or in other words two scales are equivalent with precision to a partial endomorphism $\gamma \in G_R^k(f_\theta(A))$. The elements of $G_R^k(f_\theta(A))$ are called *admissible manipulations* of the scale f_θ . An example is the measurement of the temperature. The scale $f_\theta(\cdot)$ is the temperature in Celsius. Then every partial endomorphism in this example $\gamma \in G_R^k(f_\theta(A))$ is an affine correspondence of the type $\gamma(x) = ax + b$, $a \in R$, $b \in R$ and $a > 0$, measurements done in Kelvin for example.

From the definition of the measurement and scale it follows that there are infinitely many types of scales. In informal terms measurement is an operation in which a given state of the observed object is mapped to a given denotation. An example of basic scale is the so-called *nominal scale* which is an expression of the equivalence of two phenomena only. Let X is the set of alternatives ($X \subseteq R^m$). Let x and y be two alternatives $((x, y) \in X^2)$. For this weakest scale the following axioms are valid:

1. $((x \approx y \vee \neg x \approx y) \equiv 1) \wedge ((x \approx y \wedge \neg x \approx y) \equiv 0) \wedge x \approx x$;
2. $(x \approx y \Rightarrow y \approx x)$;
3. $((x \approx y \wedge x \approx z) \Rightarrow y \approx z)$.

Here $(\approx)$ denotes equivalence and $\neg(\approx)$ is the opposite (non-equivalence). In this scale only the Kronecker symbol may be used as a measure.

In the case when the observed phenomenon allows not only to distinguish the differences between states but to compare them by preference a stronger scale needs to be used – the *ordering scale*. The preference in the ordering scale is denoted by $(x \succ y)$. In accordance with a tradition, $x \succ y$ is taken to represent “ x is better than y ”. In this scale together with the above three axioms two more are satisfied:

4. $\neg(x \succ x)$ for $\forall x \in X$, $((x \succ y) \Rightarrow \neg(y \succ x))$;
5. $(x \succ y \wedge y \succ z) \Rightarrow x \succ z$.

If incomparable alternatives exist, then the scale is called a scale of *partial ordering*. Under these five axioms an analytical representation by value function $u(\cdot)$ is searched for. A “*value function*” is a function $u(\cdot)$ for which it is fulfilled $((x, y) \in X^2, x \succ y) \Leftrightarrow (u(x) > u(y))$. In this definition, in addition to axioms (4, 5), weak connectedness is also assumed $\neg(x \approx y) \Rightarrow ((y \succ x) \vee (x \succ y))$. The definition could be restricted to the following formula in the case of partial ordering $((x, y) \in X^2, x \succ y) \Rightarrow (u(x) > u(y))$. The assumption of existence of a value function $u(\cdot)$ leads to the *negatively transitive* and *asymmetric* relation $(\succ)$ (*weak order*). Consequently the assumption of existence of a value function $u(\cdot)$ leads to the existence of: asymmetry $((x \succ y) \Rightarrow \neg(x \succ y))$, transitivity $((x \succ y) \wedge (y \succ z) \Rightarrow (x \succ z)$, and transitivity of the “indifference” relation $(\approx)$. It is proven in Fishburn (1970) that the existence of a “*weak order*” $(\succ)$ over X leads to the existence of a “*strong order*” over $X/\approx$ (“*strong order*” is a “*weak order*” for which is fulfilled $(\neg(x \approx y) \Rightarrow ((x \succ y) \vee (x \prec y)))$). Consequently the assumption of existence of a value function $u(\cdot)$ leads to the existence of: asymmetry $((x \succ y) \Rightarrow \neg(x \succ y))$, axiom 4), transitivity $((x \succ y) \wedge (y \succ z) \Rightarrow (x \succ z)$, axiom 5) and transitivity of the “indifference” relation $(\approx)$ (axiom 3).

Depending on the type of the function – continuous, partially continuous or discrete – there are

different types of scales measuring the above relations. A transformation with an arbitrary monotonous function (*admissible manipulations* $\gamma, \gamma \in G_B(f_0(A))$) of the ordinal scale leads to an ordinal scale. When using those scales, apart from comparison by magnitude, we can search the minimum and maximum of the function as feasible mathematical operations. In this manner the reader can move from the language of binary relations and preferences to the language of control criteria as objective value function.

If together with the ordering of the alternatives the distance between them can be evaluated, we can talk about *interval scale*. For these scales the distances between the alternatives have the meaning of real numbers. The mathematical expectation depends on the origin of the scale and thus is unfeasible for these scales. The transition ($\gamma \in G_B(f_0(A))$) from one interval scale to another is achieved with affine transformation $\mathbf{x} = \mathbf{a}\mathbf{y} + \mathbf{b}$, $(\mathbf{x}, \mathbf{y}) \in \mathbf{X}^2$, $\mathbf{a} > 0$, $\mathbf{b} \in \mathbf{R}$. Among these type of scales is also the measurement of the utility function by the “gambling approach” (Raiffa, 1968; Keeney & Raiffa, 1993). It is emphasized that here the calculations are done with numbers related to the distances between the alternatives.

A stronger scale is the *ratio scale*. This is an interval scale with fixed origin $\mathbf{x} = \mathbf{a}\mathbf{y} + \mathbf{b}$, $(\mathbf{x}, \mathbf{y}) \in \mathbf{X}^2$, $\mathbf{a} > 0$. Such is the scale for measuring weight. A utility function could be normed between 0 and 1 with a affine transformation and by this way transformed in *ratio scale*. For these scales the mathematical expectation is sensible evaluation and has physical meaning. For these scales in addition the following axioms are satisfied:

6. $(x = y \wedge z > 0) \Rightarrow ((x + z) > y)$;
7. $x + y = y + x$;
8. $(x = y \wedge z = q) \Rightarrow (x + z = y + q)$;
9. $q + (x + y) = (q + y) + x$.

The *absolute scale* is the most powerful. For it the zero and one are absolute and it is one of a kind and unique scale.

Depending on the way by which the empirical information for the preferences of the DM is derived the functions representing the DM's preferences $(x \succ y)$ as *value or utility* are defined (Keeney & Raiffa, 1993). Let $\mathbf{X}$ is the set of alternatives ($\mathbf{X} \subseteq \mathbf{R}^m$). A “value” function is a function ($u^*: \mathbf{X} \rightarrow \mathbf{R}$) for which it is fulfilled: $((x, y) \in \mathbf{X}^2, x \succ y) \Leftrightarrow (u^*(x) > u^*(y))$. A weaker case is when the following condition is fulfilled instead: $((x, y) \in \mathbf{X}^2, x \succ y) \Rightarrow (u^*(x) > u^*(y))$. For a finite set of alternatives and partial ordering (axioms 4, 5) there always exists such a function with precision up to monotonous transformation. In this manner from the language of binary relations and preferences is moved to the language of control criteria. Let $\mathbf{A}_u^*$ and $\mathbf{B}_u^*$ are the sets:

$$\mathbf{A}_{u^*} = \{(x, y) \in \mathbf{R}^{2m} / (u^*(x)) > u^*(y)\},$$

$$\mathbf{B}_{u^*} = \{(x, y) \in \mathbf{R}^{2m} / (u^*(x)) < u^*(y)\}.$$

If there is a function $\mathbf{F}(x, y)$ of the form $\mathbf{F}(x, y) = \mathbf{f}(x) - \mathbf{f}(y)$, positive over $\mathbf{A}_{u^*}$ and negative over $\mathbf{B}_{u^*}$, then the function $\mathbf{f}(x)$ is a value function equivalent to the empirical value function $u^*(.)$. Such approach permits the use of stochastic “pattern recognition” for solving the problem. In the deterministic case it is true that $\mathbf{A}_{u^*} \cap \mathbf{B}_{u^*} = \emptyset$. In the probabilistic case it is true that $\mathbf{A}_{u^*} \cap \mathbf{B}_{u^*} \neq \emptyset$ (Pavlov & Andreev, 2013).

From practical point of view the empirical system of relations is $\mathbf{SR}(\mathbf{X}, (\approx), (\succ))$, where $(\approx)$ can be considered as the relation “indifferent or equivalent”, and $(\succ)$ is the relation “prefer”. We will look for equivalency of the empirical system with the system of relations ($\mathbf{R}$ -real numbers, $(=)$, $(>)$). The “indifference” relation $(\approx)$ based on $(\succ)$ is defined by $((x \approx y) \Leftrightarrow \neg((x \succ y) \vee (y \succ x)))$.

MAIN FOCUS

Value based decision making bases on preferences representation by utility/value functions. As a direction of value driven design the normative ap-

proach and in particular the utility/value functions permit inclusion of the DM mathematically in the modeling and in the main objective function. It is desirable that the objective function presents all important attributes of a system being designed and outputs a score. At the whole system level, the objective function, which performs this assessment of value, is called a “value model”. In this aspect the Utility theory is the normative approach in decision making in the conditions of risk and uncertainty.

Utility Function and Measurement Scale

There are different systems of mathematical axioms that give sufficient conditions of a utility function existence. The most famous of them is the system of *von Neumann and Morgenstern's axioms* (Fishburn, 1970). According to *Utility theory* let X be the set of alternatives and P is a set of probability distributions over X and $X \subseteq P$. A utility function $u(\cdot)$ is any function, which fulfills the following:

$$(p \succsim q, (p, q) \in P^2) \Leftrightarrow (\int u(\cdot) dp \geq \int u(\cdot) dq).$$

The interpretation is that the integral of the utility function $u(\cdot)$ is a measure concerning the comparison of the probability distributions p and q defined over X . The notation $(\succsim)$ expresses the preferences of DM over P including those over $X (X \subseteq P)$. It is known that the assumption of existence of a value function $u(\cdot)$ leads to the “negatively transitive” and “asymmetric” relation $(\succsim)$ and to transitivity of the relation $(\approx)$. So far we are in the *ordering scale*. The assumption of equivalence with precision up to affine transformation has not been included. In other words there is only a value function. For value, however, the mathematical expectation is unfeasible, but we underline that the mathematical expectation is included in the definition of the utility function. For this reason it is accepted that $(X \subseteq P)$ and that P is a convex set $((q, p) \in P^2 \Rightarrow (\alpha q + (1-\alpha)p) \in P, \text{ for } \forall \alpha \in [0,1])$. Then utility $u(\cdot)$ is determined with the accuracy of an affine transformation (interval scale) (Fishburn, 1970):

$\forall \alpha \in [0,1]$. Then utility $u(\cdot)$ is determined with the accuracy of an affine transformation (interval scale) (Fishburn, 1970):

PROPOSITION 1: If $((x \in X \wedge p(x)=1) \Rightarrow p \in P)$ and $((q, p) \in P^2 \Rightarrow ((\alpha p + (1-\alpha)q) \in P, \alpha \in [0,1]))$ are realized, then the utility function $u(\cdot)$ is defined with precision up to an affine transformation: $(u_1(\cdot) \approx u_2(\cdot)) \Leftrightarrow (u_1(\cdot) = au_2(\cdot) + b, a > 0)$.

Now it is obvious why in practice the gambling approach is used to construct the Neumann utility in *interval scale*. The reason is that to be in the interval scale the set of the alternatives for comparison must be convex. A “lottery” is called every discrete probability distribution over X . It is denoted as $\langle x, y, \alpha \rangle$ the lottery: α is the probability of the appearance of the alternative x and $(1-\alpha)$ - the probability of the alternative y . In practice the utility function is measured by the gambling approach, comparisons between lotteries (Keeney & Raiffa, 1993). Weak points of this approach are violations of the transitivity of the relations and the so called “certainty effect” and “probability distortion” identified by Kahneman and Tversky (Cohen & Jaffray, 1988). The violations of the transitivity of the relation $(\approx)$ also leads to declinations in the utility assessment. All these difficulties explain the DM behavior observed in the Allais Paradox (Allais, 1953).

Stochastic Approximation and Utility Evaluation

It is assumed that $(X \subseteq P), ((q, p) \in P^2 \Rightarrow (\alpha q + (1-\alpha)p) \in P, \text{ for } \forall \alpha \in [0,1])$ and that the utility function $u(\cdot)$ exists. Two sets are used, motivated by Proposition 1:

$$A_{u^*} = \{(\alpha, x, y, z) / (\alpha u^*(x) + (1-\alpha)u^*(y)) > u^*(z)\},$$

$$B_{u^*} = \{(\alpha, x, y, z) / (\alpha u^*(x) + (1-\alpha)u^*(y)) < u^*(z)\}.$$

The notation $u^*(\cdot)$ in the sets A_{u^*} and B_{u^*} is the empirical DM's utility function. The utility

function is evaluated by recognizing the above sets with stochastic recurrent procedures (Pavlov & Andreev, 2013).

The following proposition is in the foundation of the used *stochastic approximation*.

PROPOSITION 2: Denote by A_{u^*} the set $A_u = \{(\alpha, x, y, z) / (\alpha u(x) + (1-\alpha)u(y)) > u(z)\}$. If $A_{u_1} = A_{u_2}$ and $u_1(\cdot)$ and $u_2(\cdot)$ are continuous functions than is true $(u_1(\cdot) = au_2(\cdot) + b, a > 0)$.

The approximation of the utility function is constructed by pattern recognition of the set A_u and is machine learning based on the DM's preferences. The machine learning is a probabilistic pattern recognition, because $(A_{u^*} \cap B_{u^*} \neq \emptyset)$ and the utility evaluation is a stochastic approximation with noise (uncertainty) elimination (Aizerman et al., 1970). The following presents the evaluation procedure: *The DM compares the "lottery" $\langle x, y, \alpha \rangle$ with the simple alternative $z, z \in Z$ ("better- $\setminus, f(x, y, z, \alpha) = 1$ ", "worse- $\setminus, f(x, y, z, \alpha) = -1$ " or "can't answer or equivalent- $\sim, f(x, y, z, \alpha) = 0$ ", $f(\cdot)$ denotes the qualitative DM's answer). This determines a learning point $((x, y, z, \alpha), f(x, y, z, \alpha))$. The following stochastic algorithm constructs the utility polynomial approximation $u(x) = \sum_i c_i \Phi_i(x)$:*

$$c_i^{n+1} = c_i^n + \gamma_n \left[f(t^{n+1}) - \overline{(c^n, \Psi(t^{n+1}))} \right] \Psi(t^{n+1}),$$

$$\sum_n \gamma_n = +\infty, \sum_n \gamma_n^2 < +\infty, \forall n, \gamma_n > 0.$$

The following notations are used: $t = (x, y, z, \alpha)$, $\psi_i(t) = \psi_i(x, y, z, \alpha) = \alpha \Phi_i(x) + (1-\alpha) \Phi_i(y) - \Phi_i(z)$, where $(\Phi_i(x))$ is a family of orthogonal polynomials. The coefficients c_i^n take part in the polynomial presentation $g^n(x) = \sum_{i=1}^n c_i^n \Phi_i(x)$ and

$$\begin{aligned} (c^n, \Psi(t)) &= \alpha g^n(x) + (1-\alpha)g^n(y) - g^n(z) \\ &= G^n(x, y, z, \alpha) \end{aligned}$$

is a scalar product. The line above $\bar{v} = \overline{(c^n, \Psi(t))}$ means: $(\bar{v} = 1)$, if $(v > 1)$, $(\bar{v} = -1)$ if $(v < -1)$ and $(\bar{v} = v)$ if $(-1 < v < 1)$. The following decomposition of the expert function $f(x, y, z, \alpha)$ is true:

$$f(t^{n+1}) = \left[D'(t^{n+1}) + \xi^{n+1} \right].$$

In the formula ξ denotes the uncertainty in the expert's answers. The DM relates intuitively the "learning point" (x, y, z, α) to the set A_u with probability $D_1(x, y, z, \alpha)$ or to the set B_u with probability $D_2(x, y, z, \alpha)$. The probabilities $D_1(x, y, z, \alpha)$ and $D_2(x, y, z, \alpha)$ are the mathematical expectation of $f(x, y, z, \alpha)$ over the set of positive answers- A_u and over the set of negative answers- B_u , respectively: $D_1(x, y, z, \alpha) = M(f/x, y, z, \alpha)$, if $M(f/x, y, z, \alpha) > 0$, $D_2(x, y, z, \alpha) = (-M(f/x, y, z, \alpha))$, if $M(f/x, y, z, \alpha) < 0$. Let $D'(x, y, z, \alpha)$ are the random value: $D'(x, y, z, \alpha) = D_1(x, y, z, \alpha)$, $M(f/x, y, z, \alpha) > 0$; $D'(x, y, z, \alpha) = (-D_2(x, y, z, \alpha))$, $M(f/x, y, z, \alpha) < 0$; $D'(x, y, z, \alpha) = 0$, $M(f/x, y, z, \alpha) = 0$. It is approximated $D'(x, y, z, \alpha)$ by a function of the type: $G(x, y, z, \alpha) = (\alpha g(x) + (1-\alpha)g(y) - g(z))$, $g(x) = \sum_i c_i \Phi_i(x)$ and the function $g(x)$ is an approximation of the utility $u(\cdot)$. The $G^n(x, y, z, \alpha)$ is positive over A_u and negative over B_u depending on the degree of approximation of $D'(x, y, z, \alpha)$. The convergence of the stochastic procedure is described in Pavlov & Andreev (2013). The learning points $((x, y, z, \alpha), f(x, y, z, \alpha))$ could be set with a pseudo random sequence.

SOLUTIONS AND RECOMMENDATIONS

Optimal Portfolio Utility Allocation

The proposed approach is demonstrated in a complex economical problem with human participation. The optimal portfolio allocation problem is discussed repeatedly in the economic literature (Touzi & Tourin, 2012). The construction of the objective utility function remains aside of discussions. In this example is assumed that the outcome set is a two-attribute product set $V \times W$, where V designates the first attribute - the amount π_t , $(X_t \pi_t, \pi_t \in [0, 1])$ invested in a risky process and W designates the quantity of money in BGN's. It is found that preferences on W do not depend on the particular deterministic level at which $v \in V$ is fixed. A convenient implication of this utility independence is that changing v does not affect rank-ordering in W . This determines the form of the two attribute utility $U(v, w) = U(v, w^0) + [U(v, w^*) - U(v, w^0)]U(v^0, w)$ (Keeney & Raiffa, 1993). Each of these single attribute utility functions is evaluated based on consumer's preferences (Figure 1). The ciseaux line is a sample of stochastic optimal control.

Consider a non-risky asset S_0 and a risky one S . The Black-Scholes dynamic model represents a stochastic differential equation determined by:

$$dS_t^0 = S_t^0 r dt \quad \text{and} \quad dS_t = S_t \mu dt + \sigma dW_t.$$

In the formula, μ and σ are constants ($r=0.03$, $\mu=0.05$ and $\sigma=0.3$) and W is one dimensional Brownian motion. By X_t it is denoted the state space vector of the controlled process. The investment policy is defined by a progressively adapted process $\pi = \{\pi_t, t \in [0, T]\}$, where π_t represents the risky amount $(X_t \pi_t, \pi_t \in [0, 1])$ invested at any moment t . The remaining wealth $(X_t - \pi_t X_t)$ is non-risky invested. The time period T is 50 weeks. The self-financing satisfies the stochastic differential equation (Touzi & Tourin, 2012):

$$\begin{aligned} dX_t^\pi &= \pi_t X_t^\pi \frac{dS_t}{S_t} dt + (X_t^\pi - \pi_t X_t^\pi) \frac{dS_t^0}{S_t^0} \\ &= (r X_t^\pi + (\mu - r) \pi_t X_t^\pi) + \sigma \pi_t X_t^\pi dW_t \end{aligned}$$

The amount $X_t^{x, \pi}$ is the solution of the stochastic differential equation with initial wealth (x) at time t . The main objective of the DM is maximization of the expected utility at the final moment T ,

$$V(t, x) := \sup_{\pi \in [0, 1]} E[U(X_T^{t, x, \pi})].$$

Figure 1. Utility objective function and optimal control

Figure 2. Hamilton-Jacobi-Bellman function

Figure 3. Control MANIFOLD

The control input is the amount π_t invested in the risky process. The optimal control is determined from the Hamilton-Jacobi-Bellman partial differential equation

$$\frac{\partial w}{\partial t}(t, x) + \sup_{\pi \in [0,1]} [(rx + (\mu - r)\pi x) \frac{\partial w}{\partial t}(t, x) + \frac{1}{2} \sigma^2 \pi^2 x^2 \frac{\partial^2 w}{\partial x^2}(t, x)] = 0,$$

following the dynamical programming principle. By passing through generalized solution of the

Black-Scholes stochastic differential equation it is determined a polynomial approximations of the Hamilton-Jacobi-Bellman (HJB) function $w(t, X)$. From HJB surface it is determined the control law manifold $\pi(t, X)$. They are shown in Figures 2 and 3. In Figure 4 it is shown the risk process without control.

The stochastic control is started in 30 different initial points; from 1000 BGN's to 30000 BGN's. In the next Figures 5 and 6, the processes with optimal stochastic control and a sample of 30 optimal control laws are shown.

Figure 4. Process without control

Figure 5. Process with control

The optimal control is in agreement with the DM's preferences and is significant only for this DM.

FUTURE RESEARCH DIRECTIONS

The preferences representation of the DM is an essential stage in the construction of models used in decision theory and operations research. The publications concerning preferences utility representations and their applications in economic, medicine, ecology, engineering etc. quickly grew

in the last decade (La Red Martinez & Acosta, 2015; Wakker, 2010; Kangas, 2015). One of the main obstacles in this direction is the lack of mathematical algorithms suitable for computer realization. The proposed approach is a possible solution. A serious challenge in the utility theory application is the possibility for decomposition of the multi-attribute utility into single-attribute functions (Keeney & Raiffa, 1993). A perspective idea for a new interpretation of the notion „independence” and possibilities for utility decomposition is proposed by Abbas and Bell (2011).

Figure 6. Samples of optimal control

New achievement in this direction will facilitate considerably the application of the utility theory.

Several non-expected utility theories have been developed in response to the transitivity violations of the preference (Kahneman & Tversky, 1979; Wakker, 2010). Among these theories the rank dependent utility model and cumulative prospect theory are currently the most popular. In the rank dependent utility the decision weight of an outcome is not just probability associated with this outcome. It is a function of both probability and the rank of the alternative. The declination of the probability assessment, the probability distortion has a S-shaped form closed to symmetry. The mentioned peculiarities give a hint for investigations of the process of preferences evaluation as a function of both subjective probability (in the lottery) and rank of the alternative (Machina, 2009). In the classical theory and in the neo-Bayesian approach the utility function is determined in the sense of von Neumann, with precision up to affine transformation. The problem appears when the „state of natures” is connected with human appreciation described with subjective probabilities (Fishburn, 1970; Schmeidler, 1989). This theoretical findings permit deduction that the gambling utility evaluation remain valid, having in mind the certainty effect (Cohen & Jaffray, 1988). The proposed stochastic procedures permit

sufficiently precise evaluation of the utility functions as a function of both probability and rank (Pavlov & Andreev, 2014). The certainty effect is considerably eliminated due to the nature of the stochastic procedures and due to the S shaped form of the probability distortion. The uncertainty of subjective preferences could be regarded as a noise that is eliminated as typical for the stochastic approximation. Thus the polynomial approximation is approximation of the von Neumann utility defined in classical and neo Bayesian theory with precision up to affine transformation.

CONCLUSION

The suggested approach can be regarded as a realization of the prescriptive *decision making*. The utility function is an abstraction presented in the limits of the normative approach, the axiomatic systems of von Neumann. Here is revealed the existence of a mathematical expectation measured in the interval scale on the base of the DM's preferences. This mathematical expectation could be interpreted as an approximation of the Von Neumann's utility function.

This stochastic approach permits inclusion of the DM in the objective function mathematically and in the modeling of complex processes. The

analytical representation of the human preferences and the stochastic machine learning allow practitioners to take advantage of individual application of achievements of decision making theory in various fields of human activities.

KEY TERMS AND DEFINITIONS

Decision Making: A complex and incompletely understood process which addresses the qualitative or intuitive aspects of human behavior and makes a claim for the potential of computer-based applications to a decision maker's qualitative cognitive processes.

Expected Utility Theory: It is the kernel of normative approach for answering of the question how people should rationally make choice under uncertainty.

Measurement Theory: A branch of applied and theoretical mathematics that is useful in measurement and data analysis.

Stochastic Programming: Subfield of mathematical programming that considers optimization in the presence of uncertainty.

Value Based Decision: Enable the assessment of a value for every design option so that options can be rationally compared and a choice taken. At the whole system level, the objective function which performs this assessment of value is called a “value model”.

Value-Driven Modelling: A modelling strategy that bases on an environment which enables optimization by providing designers with an objective function. The objective function inputs all the important attributes of the system being designed, and outputs a score.

Rough-Set-Based Decision Model for Incomplete Information Systems

INTRODUCTION

The increasing use of computers and information are getting necessity with increased expertise and digital data storage, that becomes compulsory and importance for usage. Rapidly increasing data traffic has revealed a major case for efficient manner with the use of the big data. Developed algorithm and suggested model can help using of the data in database structure and evaluate and process of the data for taking managerial decisions with rough sets approach. Rough sets derived from the fuzzy logic approach to perform the analysis of the incomplete information and uncertain structure. In 1982, this approach proposed by Pawlak, for discover the knowledge from big databases which is used in classification of the attributes recently. Also, Rough set is made as incomplete, inadequate and vague information organizing; it makes it suitable for data analysis (Pawlak, 1994, 1995).

Databases use this data and evaluate managerial decisions in the process of data mining has become imperative that we give the name of the emergence of the field. The rough set is a concept derived from the fuzzy logic approach to carry out the analysis of structures with uncertain data mining techniques. The decision will be developed in conjunction with computerized decision support model, giving more efficient automation systems with algorithms that are targeted. Our suggested decision support system covers the inputs, user

knowledge and expertise, outputs and decision components. In addition, data access, interactive mode, adaptability and flexible mode provides the solve problems and make decision process for certain and uncertain data with suggested rough set based algorithm structure.

This paper presents rough set based decision model, a process in which the suggested algorithm and decision support model and evaluate with the knowledge in databases and the knowledge received externally. The following sections include some necessary literature review and the rough based decision model approach. Then follow the future trends and the conclusion.

BACKGROUND

Rough set theory is an extension of set theory which proposed by Pawlak (1991) for describe and classify the incomplete or insufficient information. Besides it is mathematical tool that overcome the uncertainties and doubts. Also it verifies logic, and allows inconsistent data and no certainty to the discovery of incomplete implications. It is made as incomplete, inadequate and vague information by organizing. Rough set organizes the suitable data for analysis.

In real-world applications may includes the some uncertain and incomplete attributes in the knowledge representation systems in dynamic

situation, for this reason knowledge discovery and processing is very important for decision system. Meanwhile it is supported as a framework for conceptualizing and analyzing certain and uncertain types of data that is a powerful tool for discovering patterns with upper and lower approximations. Some of the studies used the rough set theory with minimum vertex cover problem (Chen et al. 2015; Chen et al. 2016); interval-valued information systems (Leung et al. 2008); intuitionistic fuzzy sets (Zhang et al. 2016; Huang et al. 2016) for knowledge discovery in feature selection (Huang et al. 2016) and rule induction (Lin et al. 2015). Shu & Qian (2015) and Yao & Zhao (2008) used the rough set theory for attribute reduction in pre-processing of the data mining and knowledge discovery. Macia-Perez et al. (2015) proposed the formal expansion of the rough set theory based algorithm for detection of the abnormal behaviour in outlier.

Nowadays, rough set theory has been demonstrated to be useful in many research areas such as knowledge discovery (Polkowski et al., 2010, Zhong, 1998; Sun et al., 2012), machine learning (Ananthanarayana et al., 2003; Pedrycz, 2013), decision analysis and support (Yao, 2010; Yao and Zhao, 2008; Pedrycz, 2014), expert systems (Tsumoto, 1998), and pattern recognition (Swinarski and Skowron, 2003). Rough set theory is also seen in the literature, which is used in conjunction with some heuristic algorithms with optimization applications (Changseok et al. 2010 and Yumin et al. 2010). Liu et al (2011) and (Nauman et al. 2016) used the probabilistic model to evaluate the clusters with rough sets approach. Zhong and Skowron (2001) proposed a rule of database in data mining. Liu et al (2011) and Fang et al. (2016) used the rough probabilistic model to evaluate the cluster approach with rough sets approach. As an example of feature extraction, Salamon and Lopez-Sanchez (2012) proposed the state-based classifier with the rough set theory for inference feature. Derrac et al (2012) used the snapshot feature in the selection process of selecting fuzzy rough set theory and proposed the algorithm with amplifi-

ers. Also rough sets used in wide applications in real life, such as evaluating of the credit ratings in the global banking industry (Chen, 2012) and developed the decision-making aid with hybrid models; tourism demand assessment (Carey et al., 2008;), identifying customer behaviours (James and Hshiung, 2010; Spiric et al, 2014) and medical applications (Tseng(Bill) et al., 2016).

Cuckoo based optimization approach is the new method for the global optimization. It inspired from the Cuckoo bird family life style. It has been proposed by Yang and Deb (2009). Rajabiou (2011) reviewed the cuckoo based optimization algorithm; Ouaraab et al. (2014) developed and the realized the initial test model for the discrete form. This study combined the rough set theory and cuckoo search algorithm for decision making model with usable and correct rules.

ROUGH SET BASED DECISION MODEL

Rough set theory is a mathematical method which used in reasoning and expert systems for information extraction. As in rough set theory is a structure in which to accept certain restrictions.

Rough set theory comes about of the incomplete, inadequate and vague information which is organizing the data for analysis. This study reviews the rough set based containing data sets that both types of missing attribute values in the trivial losses and obtains the rules, recommends issuing a new algorithm. This algorithm can be implemented the dataset and lead to obtaining appropriate rules. Rough sets, data reduction, feature selection, identification of hidden relationships in data and the conversion of the decision rule is concerned with the suggested model. In particular, machine learning, decision analysis used by obtaining information and data from databases, expert systems, decision support systems in which, wide range application areas. In particular, data evaluation and analysis of process uses the incomplete and uncertain data as fuzzy logic not statistical probability

Figure 1. Rough set components

distribution. Rough set theory uses the upper and lower approach (Pawlak et al., 1995; Yao, 2001; Avşar, 2007). Suggested algorithm designed in decision support system which provides support to managers through advanced analysis models in the granting of semi- structured and unstructured qualified decision. Also, it is comprised of three main components which are data, model, and dialogue. Analyzing the data model created and rough set approach used in the decision support system. In particular, data evaluation and analysis process used the statistical probability distribution. Using the upper and lower rough set theory approach preferred the determination of the rules. Fig.1 represents the classical rough set schematic structure. It is shown the boundary; lower and upper approximation; sensitivity degree borders and core region. It can show and help to understand how uncertain or incomplete data evaluate with the rough set approach easily (Pawlak, 1991; Guo and Chankong (2002). Determination and evaluation of the upper and lower bound degrees we can use the cuckoo optimization algorithm for the best solution in a short time.

The Cuckoo based algorithm inspired from the Cuckoo bird family life style. It has been proposed by Yang and Deb in (2009). The algorithm matches the nest and similarly each individual attribute of the pattern corresponds to a Cuckoo-egg. The general system-equation of the Cuckoo algorithm based on the general system-equation of the random-walk algorithms with Levi flight which is a random walk that defined with step-lengths and have a certain probability distribution which steps are being isotropic and random. It is given in Eq. 1;

$$X_{g+1,i} = X_{g,i} + \alpha \otimes \text{levy}(\lambda) \quad (1)$$

Egg laying and breeding represent their main characteristics which has been the basic motivation for development of this new evolutionary optimization algorithm. Mature cuckoos and eggs are the main components of the suggested algorithm. The main aim is survival competition some of the Cuckoos or their eggs, demise. The survived cuckoo societies immigrate to a better environment and start reproducing and laying eggs.

        Get a cuckoo (say i) randomly by Levyflights;
    Evaluate its quality/fitness  $F_i$ ;
        Choose a nest among  $n$  (say j) randomly;
        if ( $F_i > F_j$ )
            Replace j by the new solution;
        End
        A fraction (pa) of worse nests are abandon and
        new once are built
        Keep the best solutions (or nests with quality solutions);
        Rank the solutions and find the current best;
    End while
Post-process results and visualization;
End

```

Cuckoos' survival effort hopefully converges to a state that there is only one cuckoo society, all with the same profit values. During the analysis of the system, following steps are considered.

- Determination of the information system.
- Definition of the distinctive Matrix.
- Discrimination relationship with Cuckoo algorithm.
- Realizing of the reduction.
- Forming of the decision rules.
- Classification of the new features.

Determination of the Information System

Information system is a table in which rows consist of the units (samples) and in column includes the each unit features. S represents the information system and $S=\langle U, A, V \rangle$ consists of the U is a Units set, A symbolizes the conditional attributes of the each unit, V represents the each units attribute value. Any character of the attribute value is

$$a : U \rightarrow V_a, \quad \forall a \in A \quad (2)$$

(Lee ve Vatchsevanos, 2002). V_a is the a 's value set.

Definition of the Distinctive Matrix

In S information system, $M(A)=(m_{ij})_{n \times n}$ represents the distinctive matrix for A attributes. $M(A)$ can shown in

$$M(A) = \left\{ \begin{matrix} \Phi \\ a \in A : a(x_i) \neq a(x_j) \end{matrix} \right\} \quad (3)$$

$M(A)$ has distinctive symmetric matrix characteristics. Each element of the x_i and different x_j values compromise the $M(A)$. Distinctive matrix shows the binary comparison result of the attributes different values.

Applying Cuckoo Algorithm for Discrimination of Relationships

In rough set discrimination relationship represents two approach which are upper and lower approaches. We can able to use the Cuckoo optimization algorithm to determination of the alternative upper and lower solutions for beginning points. Rules induced from the lower approximation concept certainly describe the rules, which are called certain. On the other hand, rules induced from the upper approximation of the concept describe the concept possibly, so these rules are called possible.

Rough set approach is based on two concepts called upper and lower approach defined as follows:

- Elements are strictly belong to related set.
- Elements are likely to belong to related set.

$\underline{X}$ represents the lower approach which includes the certain that the interior value and it combines the primary cluster.

$$\underline{AX} = \{x_i \in U \mid [x_i]_{Ind(A)} \subset X\} \quad (4)$$

$\overline{X}$ upper approach, in the form of demonstrations and the intersection of the empty set's combination of the non-primary cluster with X.

$$\overline{AX} = \{x_i \in U \mid [x_i]_{Ind(A)} \cap X \neq \emptyset\} \quad (5)$$

Realizing of the Reduction

- **Reduced Feature Sets:** It represents the data structure in information system with minimum feature set values.
- **Core Feature Sets:** It occurs from the reduced features set's shared elements.
- **Similarity Matrix:** Reduced feature sets used the similarity matrix with reduced feature sets elements. It is logical function and used the AND and OR functions.

Reduced feature sets and information system can defined lesser than feature. Realizing minimum feature sets represent the rule base.

Forming of the Decision Rules

$D = (U, A \cup \{d\}, V)$ decision system is represented by D's degree of the $r(d)$. d decision features' values equal to the counts of the set elements, which is including the degree of D $r(d)$ are indicated with $r(d)$, the value of d is equal to the number of elements in a set of decision attributes. d decision feature set value is V_d decision feature values set is $\{V_A^1 \cup \dots \cup V_A^{r(d)}\}$. d decision feature, U units set is the

$$CLASS_A(d) = \{X_A^1 \dots X_A^{r(d)}\}$$

and

$$X_A^k = \left\{ x \in U \mid d(x) = V_d^k \right\}, 1 \leq k \leq r(d) \quad (6)$$

X_A^k is the k th decision feature value and decision class. Two unit values has the same decision feature value belong to the same decision class and represents with the U unit set is $\{X_A^1 \cup \dots \cup X_A^{r(d)}\}$.

Validation Test of the Features Dependencies

Dependency of the feature is between coefficient of the A conditional features set and d decision features that are represented with $\gamma(A, d)$.

$$\gamma(A, d) = \frac{|POS_A(d)|}{|U|} \quad (7)$$

$\gamma(A, d)$ have between 0 and 1 values. $\gamma(A, d) = 1$ is the decision feature value which depends on the A conditional feature sets. If $\gamma(A, d) \leq 1$ then d decision feature values depends on the semi A conditional features set. In Listing 2, suggested algorithm of rough set based decision model is introduced.

Listing 2. Algorithm of cuckoo search based rough set decision model

Input: Each m feature valued and C class set member's n objects, U missing quantitative value data sets.

Output: Strict and possible rough rule set

Step 1: Label of class consider the discrete feature sub set and divide each other. Same C_i class's objects represent X_i .

Step 2: $v^{(i)}$ represents the each $Obj^{(i)}$ objects quantitative values for each A_i $i=1$ to n until $j=1 \dots m$. Function values shown as follows:

$$\left(\frac{p_{j_1}^{(i)}}{R_{j_1}} + \frac{p_{j_2}^{(i)}}{R_{j_2}} + \dots + \frac{p_{j_l}^{(i)}}{R_{j_l}} \right) \quad (8)$$

R_{jk} represents the A_j 's k th region strict value and $l (=|A_j|)$ A_j shows the region count. (*) or (?) symbols symbolize the missing values.

Step 3: Missing has unclear value with the primary cluster of qualifications. If, for this the exact possible value '=' equity class into the possible incomplete (c) format ; For trivial value (*) imprecise into each missing class equality (u) format ; Lost value for the (?) It was the object located in the same area as unclear fuzzy missing class into the equation (1) is placed. Possible values is calculated as follows: to be precise =, and 0;

$$P_{Ajk} = \text{Min } p_{jk}^{(i)} \quad (9)$$

The standard Cuckoo Search algorithm includes the three basic rules (Yang and Deb, 2009):

D

- Each cuckoo lays one egg at a time, and dumps it in a randomly chosen nest;
- The best nests with high quality of eggs (solutions) will carry over to the next generations;
- The number of available host nests is fixed, and a host can discover an alien egg with a probability $p_a \in [0, 1]$.

For simplicity, this last assumption can be approximated by a fraction p_a of the n nests being replaced by new nests (with new random solutions at new locations).

When generating new solutions x (t+1) for, say cuckoo i, a Levy flight as a local random walk is performed

$$x_i^{(t+1)} = x_i^{(t)} + \alpha \otimes L(s, \lambda), \quad (10)$$

where $\alpha > 0$ is the step size which should be related to the scales of the problem of interest. The L function as a global random walk is

$$L(S, \lambda) = \frac{\left(\sin \left(\frac{\pi}{2} \right) \right)}{s^{1+\lambda}} \quad (s \gg s_0 > 0) \quad (11)$$

In most cases, we can use $\alpha = O(1)$. The product $\otimes$ means entry-wise multiplications. Levy flights essentially provide a random walk while their random steps are drawn from a Levy distribution for large steps:

$$x_i^{(t+1)} = x_i^{(t)} + \alpha \otimes H(p_a - \epsilon) \otimes (x_j^{(t)} - x_k^{(t)}), \quad (12)$$

which has an infinite variance with an infinite mean. Here the consecutive jumps/steps of a cuckoo essentially form a random walk process which obeys a power-law step length distribution with a heavy tail.

In this case, the host bird can either throw the egg away or abandon the nest so as to build a

completely new nest in a new location. For simplicity, this last assumption can be approximated by a fraction α of the n nests being replaced by new nests (with new random solutions at new locations). For a maximization problem, the quality or fitness of a solution can simply be proportional to the objective function.

Step 4: Start with $q = 1$. Then q determines the count of the number of the current feature with lower approach.

Cuckoo lays one egg at a time, and dumps it in a randomly chosen nest with Levy approach in this step with below loops:

```

Obtain  $C_{1,...,k}$  group solutions in the
solution space
    For  $i=1$  to  $K$ 
        Situation( $C_i$ ) =

$$\frac{\sum_{x \in C_i} f(x)}{\text{solution count}}$$

    End
aim = ArgMin $_{i \in \{1, \dots, K\}}$  average $_{(C_i)}$  [Minimization problem]
h_situation = ArgMin $i \in C_{\text{aim}}$   $f(x)$  [Minimization problem]
    For  $i=1$  to  $N$ 
        For  $k=1$  to  $d$ 
             $x_{i,k} = h\_situation\ k + \lambda * (x_{i,k} - h\_situation\ k)$ 
        End
    End
End
    
```

Step 5: Each X_i class consider the q feature in A subset value with lower approach calculate as follows:

$$A_*(x) = \{ (A_k(Obj^{(i)}), P_{A_k}(Obj^{(i)})) \mid 1 \leq i \leq n, Obj^{(i)} \in X_i, A_k^c(Obj^{(i)}) \subseteq X_i, 1 \leq k \leq |A(Obj^{(i)})| \} \quad (13)$$

A feature sub set includes the $Obj^{(i)}$, which is derived the missing similarity class value that represents $A_k^c(Obj^{(i)})$. It is the k th strict part.

Step 6: Each missing values for $Obj^{(i)}$ object calculated the following steps are followed:

- If $Obj^{(i)}$ object is the A th k combinations, which is applied lower approach to the subset, then obtained the uncertain value as follows:

$$\frac{\sum_{Obj^{(r)} \in A_k^c(Obj^{(r)})} v_j^{(r)} x p_{jk}^{(r)}}{\sum_{Obj^{(r)} \in A_k^c(Obj^{(r)})} p_{jk}^{(r)}} \quad (14)$$

$v_j^{(r)}$ is the quantity value for A_j in $Obj^{(r)}$ and $f_{jk}^{(i)}, R_B^k$ is the membership value for $v_j^{(r)}$. Thus, predicted $Obj^{(i)}$ values changed in rough sets. Rough missing equation class has zero membership values ($Obj^{(i)}, u$) or deleted ($Obj^{(i)}, l$) changed with ($Obj^{(i)}, c$). Rough missing approach evaluates the similarity class values again. In addition $Obj^{(i)}$ function applies to same process with the lower approach.

- $Obj^{(i)}$ object compares the one more than values with lower approach and postpone the prediction of the missing value until determine of the new features.

Step 7: $q = q + 1$. Then if $q > m$ then repeat Steps 5- 7.

Step 8: $Obj^{(i)}$ object has multiple missing value, which considers the maximum numerical expression to estimate the significance of uncertain value object. For estimate and process of the data go to Step 6 (a).

Step 9: Each missing a certain rules derived with the lower approach and next future data determined with the rough set approach.

Step 10: Final rule's effectiveness measures then compares the same exact condition rules and delete the equal and smaller.

Step 11: If $q = 1$ then do. q is used to count the number of missing upper approach.

Cuckoo lays one egg at a time, and dumps it in a randomly chosen nest with Levy approach in this step with below loops:

```

Obtain  $C_{1,...,k}$  group solutions in the
solution space
  For  $i=1$  to  $K$ 
    Situation( $C_i$ ) =
      
$$\frac{\sum_{x \in C_i} f(x)}{\text{solutioncount}}$$

    End
  aim = ArgMax $_{i \in \{1, \dots, K\}}$  average $_{(C_i)}$  [Maximi-
  zation problem]
  h_situation = ArgMax $_i \in C_{\text{aim } f(x)}$  [Maximiza-
  tion problem]
  For  $i=1$  to  $N$ 
    For  $k=1$  to  $d$ 
       $x_{i,k} = h\_situ-$ 
      ation  $k + \lambda * (x_{i,k} - h\_situation\ k)$ 
    End
  End

```

Step 12: Each X_l class's q quality, each subset A missing degree calculate with upper approach as follows:

$$A^*(x) = \{ (A_k(Obj^{(i)}), \mu_{B_k}(Obj^{(i)})) | 1 \leq i \leq n, A_k^c(Obj^{(i)}) \cap X_l \neq \varphi, A_k^c(Obj^{(i)}) \not\subseteq X_l, 1 \leq k \leq |A(Obj^{(i)})| \} \quad (15)$$

$A(Obj^{(i)}), Obj^{(i)}$ a set of equations derived missing subset of the class that contains $A_k^c(Obj^{(i)})$, $A(Obj^{(i)})$ the k -th class defined part of the equation.

Step 13: Rough set approach in each $Obj^{(i)}$ object of the missing upper method applied to imprecise (trivial or loss), the following steps are:

- $Obj^{(i)}$ object with missing upper approach, is assigned the k -th sub set of A feature set R_B^k in the combination of the area, which represents the missing $Obj^{(i)}$ uncertain value as follows:

$$\frac{\sum_{Obj^{(r)} \in A_k^c(Obj^{(r)}) \& Obj^{(r)} \in X_l} v_j^{(r)} x p_{jk}^{(r)}}{\sum_{Obj^{(r)} \in A_k^c(Obj^{(r)}) \& Obj^{(r)} \in X_l} p_{jk}^{(r)}} \quad (16)$$

- $Obj^{(i)}$ function, if one or more missing value is presented than finding of the feature process postponed until the missing information is estimated to have identified them.

Step 14: $q = q + 1$ and if $q > m$ then repeat Steps 11-13 otherwise Stop.

Step 15: Each X_l class missing rough class is used to upper approach for suitable degree as follows:

$$P(A_k^c(Obj^{(i)})) = \frac{\sum_{Obj^{(r)} \in A_k^c(Obj^{(r)}) \& Obj^{(r)} \in X_l} p_{jk}^{(r)}}{\sum_{Obj^{(r)} \in A_k^c(Obj^{(r)})} p_{jk}^{(r)}} \quad (17)$$

Step 16: $Obj^{(i)}$ function represents the missing rough low approach, multiple rough equality missing class introduces, use a maximum suitability measure for estimating the value of certain non-object. Estimates and processing to Step 13 (a) is performed as follows.

Step 17: Possible rules from the rough set approach evaluate subset of missing each Class A and the estimated size of the objects are derived. In addition, the measure of effectiveness for future data determined from the possible values of equality classes.

Step 18: Possible essential part of the rules are the same, which both the effectiveness and appropriateness of the measure value are equal to or less than clear, that specialized and other possible precise and rules determined.

FUTURE TRENDS

The development of decision support one of the key issues in the uncertainties and in-completed situations. The decision strategy developed in this paper provides a way for designing rough set theory are application independent, and improves the performance of decision system with possible proper decision with uncertainty. The experiments have shown that the proposed approach is effective and promising. This study focuses on an algorithm that provides valuable quantitative inferences from incomplete data sets with cuckoo search algorithm based rough set theory for decision rules. Suggested algorithm of rough set based decision model will be used in decision support system for real life applications in various aspects.

For future research, it is noted that cuckoo search algorithm based rough set based decision model involves not just modelling the data but also modelling operations on the data. Also different methodological approach in hybrid structure will be developed such as matrix based; entropy based; multi integer programming approach and feature extraction approach for alternative making decision style.

CONCLUSION

This article discusses a variety of issues in adapting rough set approach in distributed decision system. This study shows how rough set approach can be introduced to different aspects of rule execution from event detection to different situations with sensitivity analysis. Our suggested model includes the determination of information system; defini-

tion of the distinctive matrix; determination of the discrimination relationship; realizing of the reduction; forming of the decision rules; classification of the new features.

Our next work, which considers as a rough set theory with sensitivity analysis in different factors. Our suggested cuckoo search algorithm based rough set model can be applied to distributed decision system. The conditional attribute structure, discernibility matrix is shown in detail. We discussed the distributed decision information system for uncertainty and incomplete data. In addition, this algorithm is applied to data sets containing only the missing attribute value of lost species; it is found that increasing the number of rules obtained in this way and reduces the success rate. Missing attribute the increase in the number formed by the success rate of decline in large-scale and useful information obtained due to the increase in the number of rules.

KEY TERMS AND DEFINITIONS

Alternative Set Theory: It means system set theory that related the positive set theory and constructive set theory.

Attribute: Refers with decision table in rough set which is divided into two disjoint groups called condition and decision attributes (action, results, outcome, etc.).

Cuckoo Search Algorithm: A method of global optimization based on the behaviour of cuckoos was proposed by Yang & Deb (2009). The breeding behaviour types are, laid their eggs in the host nests; if not detected and destroyed, the eggs are hatched to chicks by the hosts.

Decision Rules: It determines decision with rules under certain and uncertain conditions.

Decision Support System: It is computer based information system that support decision making activities with inputs, user knowledge and expertise, outputs and decision components.

Incomplete Information: Three types of incomplete data consists of attribute values which are lost values; attribute missing values; irrelevant concept data in attribute.

Indiscernibility Relation: It is a central concept of Rough Set Theory which relates between two or more objects identical relation in subset of the attributes.

Information System: It consists of objects and attributes that shown in table with rows-objects and columns-attributes.

Lower Approximation: It consists of all objects which surely belong to the set.

Rough Relations: Collection of such relations is closed under different binary compositions

such as, algebraic sum, algebraic product etc. for uncertainty and incomplete data.

Rough Set Theory: It is first described by Zdzislaw I. Pawlak in early 1980's. Every object of the universe of discourse some information (data, knowledge) is associated with lower and upper approximation.

Sensitivity Analysis: Analysis of the uncertainty output in system is evaluated by the different certain or uncertain input.

Upper Approximation: It contains all objects which possibly belong to the set.

Using Receiver Operating Characteristic (ROC) Analysis to Evaluate Information –Based Decision–Making

D**Nan Hu***University of Utah, USA*

INTRODUCTION

Business operators and stakeholders often need to make decisions such as choosing between A and B, or between yes and no. These decisions include, but are not limited to, whether to invest in project A versus project B, or whether to continue running a company. These are often made by using a classification tool or a set of decision rules. For example, banks often use credit scoring systems to classify lending companies or individuals into a high or low risk of default, thus helping to decide whether to grant a loan. One important question businesses need to answer is how accurate the information based on these classification tools can help them make a correct decision, or how correctly they can be used to discriminate between two groups of subjects. In this chapter, we address this important issue by presenting accuracy parameters for assessing classification tools such as test modalities, scoring systems, and prediction models. Specifically, we introduce the receiver operating characteristics (ROC) curve as a statistical tool to evaluate these modalities. The ROC curve is widely used in business optimization analysis, health policy making, clinical studies, and health economics (Kampfrath & Levinson, 2013). In the Background section, we give updated examples of using the ROC related methods for assessing decision-makings based on our most current literature review. In the Main Focus section of this chapter, we provide mathematical definitions of the classification accuracy parameters, and describe the procedure to obtain an ROC curve. In addition, we present recent statistical developments

DOI: 10.4018/978-1-5225-2255-3.ch192

in ROC curve methodologies and applications of ROC analysis in a diversity of research areas.

BACKGROUND

Business classification tools include scoring systems, predictive models, and quantitative test modalities. A classification tool is useful in business analytics only if it is shown to distinguish entities with a certain condition from those without that condition. For instance, a credit scoring system is a valuable classification tool for bankers when it can accurately classify between companies with default status (cases) and without default status (controls). A perfect test modality would categorize all default companies as cases and all non-default companies as controls. However, in practice, almost none of the testing modalities can make such a perfect classification. This implies that misclassifications can always exist and the correct classification rate may vary from one test to another. Thus, assessing classification performance among different test modalities is always a necessary step in making important business-related decisions.

MAIN FOCUS

We first define accuracy parameters of binary classification tools, and then extend the evaluation method to test modalities with continuous or discrete ordinal values. By applying accuracy parameters and ROC analysis, business analysts

can easily examine the expected downstream harms and benefits of positive and negative test results based on these test modalities, and directly link the classification accuracy to important decision making (Cornell, Mulrow & Localio, 2008).

Accuracy Parameters for Classification and Decision Making

The accuracy of decision making should be measured by comparing the decision taken by a business to the choice that would be taken in order to maximize its benefit. In this section, we introduce two basic accuracy parameters, sensitivity and specificity, and two misclassification measures, the false positive rate and false negative rate. We define accuracy parameters in the context of classifying the default status of borrowers (companies that apply for a loan). Let S denote the dichotomous true default status such that $S = 0$ represents “no default,” and $S = 1$ indicates “default.” Let Y be the value of a test modality or scoring system. We suppose that Y is also binary such that $Y = 1$ denotes the test positive for default, and $Y = 0$ indicates the test negative. In reality, companies with a positive test result are often refused for a loan. The *sensitivity* of the binary test Y is defined as the probability of test positive among companies with default status ($S = 1$). Mathematically, this probability can be expressed as

$$\text{Sensitivity} = \Pr(Y = 1 \mid S = 1),$$

where the symbol $\mid$ denotes the statistical concept of *conditioning*, the definition of which can be found in introductory statistics books such as Wasserman (2004), Chap. 1. The sensitivity of a test is also known as the *true positive rate (TPR)*. Another important accuracy parameter is the *specificity* of Y , which is defined as the probability of test negative when the default status is absent. This probability is given by

$$\text{Specificity} = \Pr(Y = 0 \mid S = 0).$$

Specificity is often used interchangeably with the *true negative rate (TNR)* in the literature. Both sensitivity and specificity are correct classification rates of a test. Since such a test may also misclassify subjects, error rates are of interest as well.

There are also two types of misclassification rates. The first is the *false positive rate (FPR)*, which is defined as the probability of test positive when the default status is absent. Mathematically,

$$\text{FPR} = \Pr(Y = 1 \mid S = 0).$$

A false positive occurs when a “refusal of loan” decision is made to companies that would never default. By examining the definitions of *FPR* and *specificity*, we note that $\text{FPR} = 1 - \text{specificity}$.

Another misclassification rate is the *false negative rate (FNR)*, which is the probability of test negative when the default status is present. This rate can be expressed by

$$\text{FNR} = \Pr(Y = 0 \mid S = 1).$$

A false negative occurs when a loan is granted to a company that later defaults on the loan. Also, we note that $\text{FNR} = 1 - \text{sensitivity}$.

Table 1 summarizes the aforementioned accuracy and misclassification parameters. The rows of this two-by-two table are split by the true default status ($S = 1$ versus $S = 0$), and columns are classified by test results ($Y = 1$ versus $Y = 0$). In each of the four cells defined by S and Y , the top row displays the frequency of the cell and the bottom row lists the mathematical equation for the accuracy parameter or misclassification rate corresponding to that cell.

Comparing Test Modalities With Binary Values

In the process of decision making, business analysts often have several candidate test modalities with binary values without knowing which modality has the best classification accuracy.

Table 1. Frequencies and mathematical equations of accuracy measures for a binary test (Y)

Test Results	Positive (Y=1)	Negative (Y=0)	Total
True Status			
Positive (S=1)	True positives A Sensitivity = $A/(A+B)$	False positives B False positive rate = $B/(A+B)$	A+B
Negative (S=0)	False negatives C False negative rate = $C/(C+D)$	True negatives D Specificity = $D/(C+D)$	C+D
Total	A+C	B+D	A+B+C+D

For example, banks often want to minimize the chance for granting loans to companies that could default. In another words, banks wish to obtain the test modality that leads to the highest sensitivity. In contrast, when evaluating new projects for investment, business owners prefer to reduce the chance of a poor investment to the greatest extent possible. That is, they need a test modality that produces the greatest specificity.

In order to compare different test modalities, historical data based on a relatively large sample is needed. Unbiased sampling from the study population is also required. To compare two different modalities, two types of study design can be adopted: unpaired design and paired design. Under the unpaired design, the two test modalities are applied to two different groups of subjects or companies. Thus, each subject experiences only one of the two tests. Under the paired study design, every subject is tested by both modalities (Pepe, 2003).

In practice, business analysts may give priority to comparing either sensitivity or specificity between tests. In order to obtain statistical significance of the comparisons, a hypothesis test on two different proportions should be used. Under the unpaired design, test for the proportions of two candidate classification modalities is asymptotically a two-sample normal test, or Z-test. Thus, when the sample size is large, we can always perform a Z-test to compare sensitivities or specificities. However, when the sample size is small, Fisher's exact test should be used. Under the paired design, McNemar's test for paired binary data should be used to compare candidate

modalities. Statistically, this is a Chi-squared test with one degree of freedom. The aforementioned hypothesis tests can be easily performed using commercial software such as SAS (SAS Institute, Inc., Cary, NC, USA) and STATA (Stata Inc., College Station, TX, USA), and the free statistical package R (www.r-project.org).

ROC Curves

Many test modalities are measured on a continuous or discrete ordinal scale. When such tests are evaluated, we cannot define their sensitivity and specificity without dichotomizing their distributions. A standard and popular tool for evaluating accuracy of these modalities is the receiver operating characteristic (ROC) curve, which has been studied or described in detail in literature such as Swets and Pickett (1982), Swets (1988), Hanley (1989), Begg (1991), Chock, Irwig, Berry & Glasziou (1997), Zhou, Obuchowski & McClish (2002), and Pepe (2003). To dichotomize the continuous distribution, we usually need to specify a *testing threshold* or *cut-point* upon which to base our decision. In this section, we use an example of classifying the default status to illustrate features of the ROC curves. There are two dimensions of an ROC curve. The first is the gold standard (GS) of the test, also known as the reference standard (RS), which is the true status being classified. It is often assumed that the GS for each observation can be confirmed without error. In assessing a credit scoring system, the true default status for each company is the GS, which can be determined based on the bank's guidelines

for default. Although a GS is binary in nature, it can also take on more than two categories. For example, in personal health assessment, the true status could be “excellent,” “very good,” “good,” “fair,” or “poor.” In order to use ROC analysis to assess risk prediction models, investigators often need to dichotomize the categorical variable. Perneger & Courvoisier (2011), in their study of assessing multi-attribute health utility measures, dichotomized the true health status as “excellent” or “very good” versus “good,” “fair,” or “poor.” Classifiers are another aspect of ROC curves. They are the measurements being used for classifications. To classify the default status, the classifier could be a credit scoring system or a risk predictive score estimated from a regression model. When the single threshold value for classifiers needed to make a decision is not known *a priori*, an ROC curve provides a useful description of accuracies for the classifiers. The ROC curve plots a test’s sensitivity versus its FPR (or 1-specificity) at each cut-point c . As the cut-point defining the positivity changes across all

possible values of the test scale, the ROC curve is plotted. In other words, an ROC curve tracks all points of sensitivity and FPR pairs at all possible threshold values. The number of points on the ROC curve is determined using the possible number of available thresholds. For continuous test results with a known distribution, there are an infinite number of cut-points from which we can choose to dichotomize the distributions of cases and controls. In this situation, the resultant ROC curve is smoothed with an infinite number of points.

To mathematically define an ROC curve, let Y be a random variable denoting the value of a test modality with the convention that higher values of Y are correlated with a higher probability of being a case. Let S denote the GS status such that $S = 1$ indicates a case and $S = 0$ indicates a control. Y_D and Y_C represent test results for cases and controls, respectively. When a cut-point value c is used to dichotomize the distribution of Y , the sensitivity and FPR are mathematically given by:

Figure 1. Distribution of test result for cases/controls and the corresponding ROC curve

$Sensitivity = Pr(Y > c \mid S = 1) = S_D(c) = 1 - F_D(c)$, and

$$FPR = Pr(Y > c \mid S = 0) = S_C(c) = 1 - F_C(c),$$

where $F_D(c)$ and $F_C(c)$ represent the distribution functions of Y_D and Y_C , respectively. If we denote the FPR at cut-point c as $FPR(c) = S_C(c) = v$, then the ROC function is defined as the corresponding sensitivity at $FPR = v$. Mathematically, this is a composite function of S_D and S_C in the following form:

$$ROC(v) = S_D(c) = S_D(S_C^{-1}(v)),$$

where $S_C^{-1}(\cdot)$ denotes the inverse function of S_C such that $S_C^{-1}(v) = c$ is equivalent to $S_C(c) = v$.

Figure 1 shows the process of making an ROC curve, and the relationship between the ROC curve and distributions of test modality Y . To recap, Y_D and Y_C are used to denote the test results for cases and controls, respectively. We assume that the test modality here is the predicted risk score from a regression model, cases represent companies that would default, and controls are companies that would not default. In Figure 1, the distribution for controls is located to the left of the distribution for cases because cases usually have higher estimated risk scores. There is an overlapping of the two distributions as represented by the shaded area. At a given threshold c , the sensitivity of the test can be visually represented by the area under the distribution of Y_D from c to the maximal value of Y_D . This sensitivity is shown on the y-axis of the ROC curve for the corresponding risk score (the right panel of Figure 1). In addition, the shaded area on the right side of c represents the probability that Y_C is greater than c , which is the FPR of the risk score and corresponds to the x-axis of the ROC curve. As the cut-points are changed over an infinite number of all possible test values, a continuous ROC curve from point (0, 0) to (1, 1) within the unit square is obtained.

ROC curves are simple and straightforward graphical tools that convey comprehensive infor-

mation about classification accuracies. Because an ROC curve is a plot across all possible decision thresholds, it does not require the specification of threshold values to generate the curve (Zweig and Campbell, 1993). It is independent of the number of cases that occur among the whole population, and it is invariant with respect to monotone transformations that keep the rank of the test score for each individual. ROC curves are monotonic and non-decreasing. An ROC curve that is located closer to the upper and left boundary of the unit square indicates better performance of the test.

Area Under the Curve

The area under the ROC curve (AUC) is an indicator of the overall accuracy of classification tools. The AUC can be interpreted in the following three ways (Zhou, Obuchowski & McClish, 2002): (1) the average sensitivity over all possible values of specificity; (2) the average specificity across all possible values of sensitivity; and (3) the overall concordance of the test values with the gold standard. Specifically, the AUC equals the probability that an underlying test value Y will assign a greater probability of being a case than that of being a control (Greenland, 2008). In this sense, the AUC is equivalent to the concordance C -statistic proposed by Harrell (2001).

Choosing the Optimal Decision Threshold

Test modalities with continuous values, by themselves, do not usually constitute compelling evidence that leads directly to either a positive or a negative decision (Swets, 1992). Rather, a cut-point needs to be specified in order to define a positive or negative decision for or against the condition being classified. In practice, a cut-point can be set anywhere along the range of the test scale such that values above the cut-point uniformly lead to a positive decision, and values below it result in a negative decision. Although an ROC curve is plotted across all possible cut-points of the test,

accuracy parameters (i.e., sensitivity and specificity) cannot be determined unless a cut-point is fully specified. This implies that the resultant test accuracies are linked to the testing threshold used in the study (Zweig & Campbell, 1993).

Choosing a particular decision threshold that is best for a given purpose or for a specific situation is not a trivial task, since many aspects of the classification need to be considered and balanced. In the area of health economics, for example, it has been argued that all related economics techniques and principles should be used to identify a testing threshold (Phelps & Mushlin, 1988; Zweig & Campbell, 1993; Laking, Lord & Fischer, 2006). First, sensitivity and specificity, as performance criteria, are highly correlated (Greenland, 2008; Sanghera, Orlando & Roberts, 2013). Thus, they cannot be considered separately, and the optimal threshold should have an appropriate balance between sensitivity and specificity (Zweig & Campbell, 1993). Consider the breast cancer screening test. While high sensitivity is required in such tests, a low specificity (or high FPR) usually cannot be tolerated, since otherwise a large proportion of healthy women will be referred to invasive confirmative tests such as biopsy. In addition, cut-points should be specified in the most cost-effective way. Many authors proposed to use costs associated with each classification rate as the major criteria. For example, Greenland (2008) pointed out that costs are a crucial element in the optimization process, and proposed the use of a cost-related loss function to define decision rules and specify optimal thresholds. In health economics studies, many authors have suggested that decision criteria should incorporate not only the cost of misclassifications but also information regarding cases and controls. Phelps and Mushlin (1988) proposed a criterion called “expected value of information” (VOI), which is a comprehensive cost-related parameter that combines decision accuracies and epidemiologic information about disease prevalence. The VOI method defines the net benefit of a decision related to a certain disease, which is the difference between the total utility of

a decision and the total cost of the decision. Then, a formula is applied to ensure that the optimal net benefit of a test modality is identified for a given disease prevalence (Altman & Bland, 1994). The results are then used to create a tangent on the ROC curve, and the point where the tangent and the ROC curve meet is the optimal cut-point. This process can be extended to accommodate a range of prevalence values, sensitivities, and specificities.

Extension to Time-Dependent ROC Analysis

When the binary decision space is a function of time, the traditional ROC analysis introduced in previous sections will no longer be adequate. For example, in assessing the performance of credit scoring systems for detecting default risk, a company’s default status can change over time. In order to accommodate this situation and obtain appropriate evaluations, a time-dependent ROC analysis should be used to assess the accuracies of the credit scoring system in a time-varying fashion (e.g., to assess the accuracy for predicting default status three years after the loan is granted). In medical decision making, time-dependent ROC analyses can be applied to evaluate the prognostic accuracy of various biomarkers for the early detection of cancers. If a prognostic tool is clinically accurate enough, doctors could make decisions based on the prognostic modality and give special treatment priority to patients with bad prognostic results. Hu & Zhou (2010) and Hu (2013) summarized the up-to-date statistical methods in time-dependent ROC analysis, and readers who are particularly interested in this issue are referred to their paper for an overview.

Applications

ROC analyses can also be used to evaluate a certain component or parameter in a credit scoring system or a prediction model. Garanin et al (2014) utilized ROC curve analysis for assessing the performance of credit decision making by testing the classifica-

tion accuracy among loan applicants. The authors used the logistic regression model to evaluate the probability of default, and used the ROC curve to test credit scoring and used logistic regression model to test the variables selection in scorecard (Garanin, Lukashevich, & Salkutsan, 2014). Vlasselaer and colleagues used the area under the ROC curve to evaluate the benefit of including certain predictor variables in the Anomaly Prevention using Advanced Transaction Exploration (AP-ATE) model that united both intrinsic features and net-work based features (Vlasselaer et al., 2015). The goal of using the APATE method is to better detect fraudulent credit card transactions by analyzing the customer past spending history and behaviors into useful meaningful features and make comparisons of those feature with a new incoming transaction. From deriving recency, frequency and monetary (RFM) characteristics-customer past incoming transactions and spending history, intrinsic features can be generated. The authors found that, when the model included only 9 network variable, the model reached an AUC of 0.92. However, when the model included all of the social network and RFM variables, the model reached the highest AUC scores of 0.987. They, thus, concluded that RFM variables are good predictors of fraud and there is a strong bind between intrinsic aspects and net-work based feature.

ROC curve analysis is also widely used in examining the performance and utility of a credit scoring system. Byanjankar and colleagues used ROC analysis to evaluate the neural network credit scoring system for detecting the borrowers' credit-worthiness in the peer-to-peer (P2P) lending (Byanjankar, Heikkila, & Mezei, 2015).

In addition, ROC analysis is intensively used in assessing the performance on recently proposed ensemble models for predicting the loan risk. Goyal & Kaur (2016) was seeking for optimum results in credit risk by using support vector machine (SVM), the random forest network, and

Tree model for Genetic Algorithm, and combining these three models (Ensemble model) to analyze the loan risk (Goyal & Kaur, 2016). They cross-validate the results by using 70% of their data as the training set and the rest 30% as the validation set. Accuracy of model was performed based on ROC and the AUC. The authors claimed that the accuracy rate was the highest, in terms of AUC, for the ensemble model, which optimize the result for loan risk prediction. Yao & Lian (2016) also proposed a SVM based Ensemble Model, named SVM-BRS. Their model combined the random subspace, boosting and SVM classifier. The authors also use AUC under the ROC curve as the metric to evaluate the classification accuracy of different models. The authors found that SVM-BRS has a better performance than a single model because SVM-BRS as it had the highest AUC of 77.4%. Figini and colleagues conducted the ROC analysis and use AUC as the metric to compute weights in aggregation probabilities in the weighting ensemble scheme, these authors also used the AUC for evaluating the prediction accuracy. Regis and Artes assessed credit card risks using multi-state Markov models by studying the attributes of different state transition in client-institution relationships over time, and proposed score models for different purposes (Regis & Artes, 2016). The authors compared the results of logistic regression to the results of multi-state Markov models using a Brazilian financial institution database (Regis & Artes, 2016). The category of a client was classified as bad when the credit score is lower or equal to a cut-point c , and as a good when the credit score is higher than c . They used area under the ROC curve to evaluate the quality of model. They authors found that the multi-state Markov models had the better performance than logistic regression models in predicting the risk of default risk, but logistic regression models had better performance when predicting the loan cancellation risk.

Applications of ROC Analysis in Areas Other Than Financial Decision Making

In addition to applications in business analytics and optimization, ROC analysis is widely implemented in medical prognosis, diagnosis (Zhou, Obuchowski & McClish, 2002; Pepe, 2003), and psychometrics (Swets, 1986; Dolle, Schulte-Körne, O'Leary, von Hofacker, Izat & Allgaier, 2012). ROC analyses have recently been extended to several business-related fields such as the analysis of economic evaluations (Laking, Lord & Fischer, 2006; Sutton, Cooper, Goodacre & Stevenson, 2008; Sanghera, Orlando & Roberts, 2013), assessment of financial parameter-derived classifiers for deciding if cloud computing should be used in projects (Kornevs, Minkevica & Holm, 2012), analysis of health administrative data (Nachev, Hill, Barry & Stoyanov, 2010; Benchimol, Manuel, To, Griffiths, Rabeneck & Guttmann, 2011), financial distress analysis (Shams, Sheikhi & Sheikhi, 2011), and examining customer churn predictions (Ballings, Van den Poel & Verhagen, 2012), analyzing credit risk of small and medium enterprises (SMEs) in China (Chen, Wang & Wu, 2010).

Particularly, with a growing focus on comparative effectiveness research and personalized medicine, ROC analysis will play a more important role in health care decision-making. Specific applications of ROC analysis in health care research include predictive model validation, biomarker diagnostics/prognostics, responder analysis in patient-reported outcomes, and comparisons of alternative treatment options (Alemayehu & Zou, 2012).

FUTURE TRENDS

With the rapid increase in the number of new decision making tools and risk predictive models, the assessment of test modalities will become a key element in business analytics, policy making,

and health economics. Benchimol, Manuel, To, Griffiths, Rabeneck & Guttmann (2011) claim that sensitivity, specificity, and the C-statistic (AUC) are among the areas of priority when designing and assessing the quality of validation studies. With the recent development of statistical methodologies in ROC regression (Pepe, 2003), AUC regression (Dodd & Pepe, 2003), and time-dependent ROC methods (Hu & Zhou, 2010), business analysts and policy makers can perform more specific analyses when assessing decision making (e.g., the covariate effect on classification accuracies and time-specific predictions).

CONCLUSION

Classification modalities, including decision making rules, test scoring, and risk predictive models, are quantitative tools that can help businesses make correct decisions. Assessing accuracy is the most important procedure in validating these tools. Sensitivity and specificity are two important aspects of classification accuracy. For a test modality with continuous or discrete ordinal values, an ROC curve plots its sensitivity versus FPR (1-specificity) across all possible decision thresholds, and the area under the ROC curve (AUC) summarizes the overall performance of the modality. To find the optimal threshold value is a challenging task, and often requires the consideration of several aspects of decision making. In presenting this topic to business owners, operating analysts, and public policy makers, we suggest that ROC analysis will become a fundamental tool in making important business and policy decisions.

KEY TERMS AND DEFINITIONS

AUC (C-Statistic): The area under an ROC curve that summarize the overall probability for correct classification.

Diagnostics Test: A quantitative test modality that is used to discriminate cases of interest from non-cases (controls).

False Negative Rate: The probability that a diagnostic test classify incorrectly a case as a control.

False Positive Rate: The probability that a diagnostic test incorrectly classify a control as a case.

Gold Standard: A standard that can specify the true status being evaluated without error (a.k.a., reference standard).

ROC Curve: A curve that plots a diagnostic test's sensitivity versus its false positive rate across all possible threshold values for defining positivity.

Sensitivity: The probability that a diagnostic test can correctly identify a true case.

Specificity: The probability that a diagnostic test can correctly specify a non-case.

INTRODUCTION

Decoding digital literacy is a descriptive act of interpreting, reinterpreting, and understanding the relationship between the terms digital and literacy in the expanding space of information and communication technologies (ICTs). While the idea of literacy reveals a long evolutionary past associated with the term literate, the construct of digital, as we use it today, is shaped by the use of the digits, 0 and 1, in the 1930s and 1940s to represent computer data—a practice that eventually came to be known as digital. With the emergence of the Internet and the Web as the dominant systems of information organization and knowledge creation, the concept of literacy was broadened from its original notion of skills in reading and writing to developing cultural, historical, social, and technical awareness—a shared assumption critical to and closely associated with the understanding of ICTs and their use as well. The shift has influenced the definition of literacy as “primarily a technology of which records are the end products” (Clancy, 1993, p. 20). Although contemporary discourse in digital literacy assumes a much expanded scope of understanding than a product view of technology, the deterministic tendencies are evident in instances in which digital literacy is viewed as a set of benchmark skills. Broadly speaking, digital literacy is couched in both “conceptual” as well as “standardized operational” definitions (Lank-shear & Knobel, 2008, p. 2), the key distinction being the former places digital literacy within the multiplicity of frameworks and models, while the latter measures and observes skills and performances that advance the “standards” of being digitally literate.

BACKGROUND

In 1981 *The Washington Post* first pioneered the concept that demanded “special skills” to use and manage computers (Warschauer 111) and invented the term “computer literacy.” Later, extension of the term “literacy” included “information literacy,” “digital literacy,” and “media literacy” to broaden the idea of skills. Paul Gilster (1997) in his pioneering book, *Digital Literacy*, popularized digital literacy as a shorthand for understanding and using information in multiple formats “from a wide range of sources presented via computers” (p.33). He operationalized and extended the term throughout the book, postulating that “digital literacy is about mastering ideas, not keystrokes” (p.1)—a call to attention between a “special kind of mindset or thinking” and “limited technical skills” (Bawden, 2008, p.19) premised on tasks and performances on the other. According to Gilster, digital literacy is about developing a critical approach toward using digital sources and forming awareness about our “expanded ability” (p.31) to connect with people and information using these sources. Over the years, digital literacy has addressed the split through skill and knowledge perspectives. Evidently, the skill construct affirms the neutrality thesis of technologies in which technologies are understood as means or instruments that need to be learned; conversely, the knowledge model ascertains technologies as more complex systems, not free of social, cultural, and political biases.

Despite these prevalent articulations, the challenges of defining digital literacy stem from a lack of consensus building among stakeholder disciplines, including education, communication studies, English, media studies, library infor-

mation studies and computing. The problem is further compounded by competing interpretive frameworks and theoretical models (Boechler et al., 2014) that stake claims on the scope and application of digital literacy. Considering the value of addressing the diverse views, the scholars have framed a discourse around digital literacy to accommodate dominant perspectives. These perspectives coalesce the domain-specific views into two broad categories that are identified as conservative, sometimes called traditional, and skeptical (Aviram & Eshet-Alkalai, 2006; Boechler et al., 2014). The former is uncritical of existing literature and accepts it in face value, privileging an instrumental view of digital literacy implicated in the notion of acquiring threshold or generic set of technical skills. This perpetuates the standardized paradigm of skill acquisition, a method common in educational institutions that aligns pedagogy through traditional conceptualizations of computer literacy (Ferrari, Punie & Redecker, 2012), information literacy (Mackey and Jacobson, 2011), and network literacy (McClure, 1994). Notwithstanding the widespread adoption of the view in curricular mapping and technology developments, the assumption is challenged as a didactic model that stabilizes teaching and learning as a set of prescriptive and durable practices that have fixed unities of time and place in which the role of technology is regarded as neutral.

The skeptical or functional approach, on the other hand, gained prevalence as a reaction to the conservative approach. The underlying thesis favors contextualization of digital literacy and by extension digital technologies, reframing digital literacy as a plural concept. As an alternative strategy, it recognizes that digital literacy cannot replace traditional learning but can enhance the learning environment. The thinking here is that the functional approach potentially erases the dichotomies between digital and print literacies by emphasizing the hidden aspects of “learning styles, multiple intelligences, personality types,” and capacities (Aviram & Eshet-Alkalai, 2006). The perspective coincides with the idea of meta-

literacy and value adds a plural approach to digital literacy discourse, facilitating a strategic inclusion of multiple critical conditions such as cross-cultural contexts (Thatcher, 2010), privacy and surveillance (Reilly, 2016), and situated learning within the wider conceptual framework.

The skeptical formulation questions the skill paradigm but also situates literacy beyond cognitive processes of reading, writing, and information seeking. In that it underlines the social dimension of literacy, emphasizing critical exchange and application of thoughts and ideas between individuals. Reframing literacy along these lines was done by a group of scholars in the 1980s and 1990s who called it “the New Literacy Studies” (NLS); there are still others who focus “on more recently developed literacy practices which are often (but not always) associated with ‘new technologies’ like computer and the Internet” (Jones & Hafner, 2012, p.13) and define it as “new literacies.” Digital literacy functions as a type of new literacies among several others, like computer literacy, Internet literacy, network literacy or hyper-literacy, and media literacy; other analogs include, Web literacy and game literacy (Buckingham, 2008); library literacy and reproduction literacy (Koltay, 2011); ICT skills, e-Skills, and ICT literacy (Lee, 2014), which all share common conceptual assumptions.

Digital literacy incorporates a strong social component reimagined through concepts like user, access, practice, consumption, interpretation, and production that gain emphasis within the contemporary literacy discourse. Importantly, there are four basic assumptions of new literacies that help to conceptualize digital literacy within a larger framework of literacy: (a) innovations in ICTs require new skills, competencies, awareness, and strategies of use; (b) new literacies develop continually as their defining technologies change (c) literacy components empower individuals as global citizens; (d) new literacies are multi-dimensional and multi-modal and their understanding positively impact our social participation (Leu et al., 2007). These assumptions underscore the critical perspective articulated by Paul Gilster (1997)

and later explained by David Bawden (2008). Similarly, others have emphasized the importance of approaching digital literacy and production from feminist perspectives (see Hawisher and Selfe, 1999; Wajcman, 2004), raising questions like online equity and subject positions, whether technological innovation equals advancement of literacy or how costs of digital technologies hinder or facilitate the learning process across social, cultural, or institutional spaces.

From a critical digital perspective, it is difficult to imagine digital literacy as a stand-alone term; the critical dimension includes the internal “faculties of analysis and judgement applied to the content, usage, and artefact of the technology” while the external critical element refers to the cultural and historical circumstances of the wider field of technology than computers (Hinrichsen and Coombs, 2013). Thus, the idea of literacy in digital literacy continues to be redefined by innovations of digital technologies and signals an opportunity to reconstruct a definition based on contextualized meaning and practices than checklist of skills.

Bawden (2008) offers an updated version of digital literacy by suggesting that “it is not sensible to reduce it to a finite number of linear stages” (p. 28). For him, the six-stage linear model for information literacy formulated by American Library Association in 1989, which had a considerable influence on the scholarship and conceptualization of digital literacy, does not adequately characterize contemporary understanding of digital literacy. Bawden formulates a digital literacy framework in the light of the changing circumstances and awareness for rapid technological innovation. It includes (a) underpinnings as literacy *per se* and computer/ICT literacy, (b) background knowledge as complex of information and nature of information resources, (c) central competencies as basic skills such as reading and understanding digital and non-digital formats, knowledge assembly, evaluation of information, etc., and (d) attitudes and perspectives as underlying concept connecting modern idea of literacy with the values of older

literacy through independent learning and moral/social responsibilities (p.29-30).

Similarly, Yoram Eshet-Alkalai (2004) encapsulates a framework with five types of digital literacy: (a) photo-visual literacy to interact with the visual-graphical interface (b) reproduction literacy to reproduce meanings by repurposing and recombining preexisting information elements; (c) information literacy to assess and evaluate the credibility of online information; (d) branching literacy to navigate the non-linear Web structure; (e) socio-emotional literacy to safeguard personal interests within the expanded scope of collaboration and networking offered by the ICTs. The framework was further updated with the real-time digital skill characterized by the ability of users to manage and respond to real-time, high-speed, and quick-response digital scenarios and genres (Eshet, 2012) such as gaming and simulation.

Both these models expand the scope of digital literacy from practice-orientated to (critical) knowledge-orientated conceptualizations. They index the idea of literacy as a discourse, embedding a complex understanding of the relationships between the tool, the environment, and the actor. The frameworks position digital literacy as a “survival skill” and explore the idea of social membership within the digital space. Most importantly, the shift from a tool-centered toward a critical knowledge orientated framework exemplifies learning as a social phenomenon external to tools or residing outside of tools and machines.

GLOBAL DIGITAL LITERACY PROGRAMMES AND POLICIES

From a policy standpoint, the emphasis placed on digital literacy training is enormous across the global societies. Initiatives by various national and international organizations, governments, and educational institutions support the continuing relevance of digital literacy. The content, strategies, and development of training programs and materials are often structured in conjunction with

the demands and needs of the target populations. For example, a macro perspective on literacy was adopted by UNESCO to guide the digital literacy policy framework that defined literacy as “a continuum of learning in enabling individuals to achieve their goals, to develop their knowledge and potential, and to participate fully in their community and wider society” (UNESCO, 2004). Further, UNESCO’s Information for All Programme³ (IFAP) recognizes digital literacy as “life skill,” outlining objectives squarely related to the more critical idea of digital literacy—“ICT skills, civic skills, learning to learn skills, and participation of adults in lifelong learning” (UNESCO, 2011). The objectives, such as these, are aptly coordinated with the support from national governments and agencies through centralized policies. Evidently, these policies vary across the geographical boundaries both from conceptualization and implementation standpoints.

In the United States, the mainstreaming of digital literacy is guided by several plans of action formulated by governmental and non-governmental agencies. According to the *Fact Sheet: Digital Literacy* report 2011, “28 percent of Americans do not use the Internet at all” (commerce.gov). Toward that end, the transformative task of building discourse communities for participating in information economy is largely facilitated by strategic interventions at K-12 levels and adult community learning centers such as the Literacy Information and Communication Systems (LINCS), a national leadership initiative of the U. S. Department of Education, Office of Career, Technical Adult Education (OCTAE), Division of Adult Education and Literacy (DAEL) (lincs.ed.gov). The compelling idea behind digital literacy education is to ensure digital inclusion by raising the quality of general awareness and critical thinking among learners—a contention echoed by the Association of American Colleges and Universities (AAC&U) in their publication, *Greater Expectations* that envisions college graduates in the role of “integrative thinkers who can see connections in seemingly disparate information

and draw on a wide range of knowledge to make decisions” (aacu.org).

Other western nations also emphasize the importance of digital education as part of their broader educational goals. For instance, the United Kingdom has in place the Digital Inclusion Strategy with the aim to reduce digital exclusion. The main implications of the plan are outlined in terms of skill acquisition, ICT connectivity, and equal accessibility. The government has adopted the Action 15 document with the stated purpose to “Collaborate with partners across public, private and voluntary sectors to help people go online” (gov.uk). On a larger scale the European Union (EU) has undertaken the Digital Literacy 2.0 funded in the “Lifelong Learning Programme” to bring Web2.0 affordances within the ambit of everyday life. The salience of digital literacy is recognized as “one of the key competences to ensure social cohesion, active citizenship and personal fulfillment” (digital-literacy2020.eu). The most comprehensive plan for enhancing citizens’ digital knowledge was envisioned by the European Commission Institute for Prospective Technological Studies. The institute’s goals are premised on the notion that “participation in the digital domain is no longer a question of ‘haves’ or ‘have nots,’ but rather an issue of competence” so much so that digital literacy is accepted as one of the eight key competencies for “Lifelong learning.” Within this context, digital literacy is identified as a “transversal key competence” that enables acquisition of other key competences like language, mathematics, learning to learn, cultural awareness, etc. The European Digital Competence Framework, the primary

instrument of implementation, contains 21 competences structured according to 5 areas: information, communication, content-creation, problem solving, and safety. A lot of emphases are laid for utilizing digital literacy for job searching process and improving employable qualifications (openeducationeuropa.eu).

Digital literacy penetration in South America presents a very different picture altogether. Ac-

cording to a World Economic Forum global technology report, the social and economic impacts resulting from ICTs are still somewhat low. Despite the efforts made by the government agencies to digitally connect its population, problems with infrastructure, political instability, regulatory policies and above all low skill base pose serious challenges (Bilbao-Osorio et al., 2013, p. 15). The ICT Development Index (IDI) 2011 of the major economies shows Argentina ranked at 56, Brazil at 60, and Mexico at 79 respectively (www.itu.int). Argentina in 2006 made a longstanding and comprehensive commitment to introduce digital literacy in educational sector especially at the secondary level. The highlights of the policy include improving computer infrastructure in classroom, training teachers to encourage adoption of digital technologies in pedagogy, developing appropriate educational content to integrate technologies, and implementing One Laptop per Child (OLPC). The Digital Literacy National Campaign, started in 2006, promotes digital literacy in conjunction with Encuentro TV channel that regularly broadcasts quality educational content to schools. Further, the creation of the national portal, www.educ.ar, facilitates teacher training, connects schools to the information superhighway, and develops and delivers digital content for education purposes (Lujambio et al., 2008, p.80-81).

Compared to South American countries, Asian economies perform better when it comes to diffusion of digital literacy. A quick survey of the Association of Southeast Asian Nations (ASEAN) reveals that all eight member-nations have progressed in the direction of digitizing social and cultural life of their citizens (Bilbao-Osorio et al., 2013, p. 15). For instance, The Digital *Saksharta Abhiyan* (DISHA) or National Digital Literacy Mission (NDLM) envisaged by the government of India in 2015 aims to bring at least one member from the household to participate and train in digital literacy. Given the complex diversity and huge population of India, the program enables the participating families to nominate one member to undergo the certificate training. In the Indian

context, digital literacy is defined as “the ability of individuals and communities to understand and use digital technologies for meaningful actions within life situations.” The introduction of the concept proceeds through two staggered levels, (a) appreciation of digital literacy which includes orientating with and operating digital devices like mobile phones and tablets, and (b) basic digital literacy which enables active citizenship through participating in e-governance (ndlm.in). In addition to government initiatives, there are numerous private agencies and organizations involved in the idea of digital literacy for the commons. The “Hole-in-The Wall Education Project (HiWEP) started by a private individual in the late 90s has over 300 learning stations for educating poor and disadvantaged children in India and Africa. Using a principle known as “Minimally Invasive Education,” HiWEP installs networked computers or learning stations in public places like streets, market places, and playgrounds with the purpose to attract and encourage young children to learn ICTs in independent, self-organizing, and sometimes collaborative environments (Mitra & Dangwal, 2010). The project has received a lot of traction among underprivileged communities where technology access is a chronic problem. HiWEP has been praised by various international organizations including UNESCO and continues to remain a crucial instrument for spreading digital literacy.

Global diffusion of digital literacy is based on the idea of strategically exposing the populations to the practical and ever changing dynamics of digital technologies. Regardless of global economic status, the digital literacy policy discourse is dominated by three fundamental optics: reach, penetration, and applicability. Reach entails closing the digital gap, penetration involves targeting to specific needs, and applicability concerns transference of competence for performing activities within social contexts. In the case of the developed nations, the quantum of applicability is very diverse and complex and is thus central to policy implementation. For most developing nations, however, the challenges are capacity

building and task prioritization and hence reach and penetration act as vital indicators. Interestingly, the global diffusion pattern reveals distinct strategies, varying across geographic, cultural, and political scales. For instance, while the EU focuses on employability aspects, the United States is more concerned with early exposures at institutional levels from K-12 upwards. Similarly in the case of South America, the emphasis lies on infrastructure while India, being a collectivist culture, attempts to create a large “family” of digital users by targeting individual households.

ISSUES AND CHALLENGES

Lack of consensus among researchers is a major hindrance to developing a theory of digital literacy that could be translated to educational contexts to serve the current generations of students. Eshet-Alkalai (2004) suggests that “indistinct use of the term causes ambiguity, and leads to misunderstanding, misconceptions, and poor communication.” In the absence of a consolidated definition, educators are faced with the challenges of curricular development and identifying proper assessment techniques consistent with students’ learning objectives; an allied problem is reorienting teachers toward embracing a philosophy of digital literacy that can ultimately address the practical and social needs of students. As the notion of literacy shifts from a text-based syntactic to a graphic and link based semantic conceptualization (Nielsen, 1993), digital literacy must be understood as a moving target because digital technologies evolve rapidly. This has led to question the assumptions whether the so called ‘digital natives’ are truly equipped to understand and use ICTs in their current iterations. The problem is more acute at the K-12 level where in absence of a unified digital literacy curriculum, the institutions are capitulating to what is referred to as the “standards movement” (Trotter, 1997 in Boechler et al., 2014) conceived by the International Society for Technology in Education (ISTE)—an

organization dedicated to “leveraging the use of technology in K-12 education” (Boechler et al., 2014). Thus, as ‘screen becomes the dominant site of texts,’ emphases are laid on measuring concepts of digital literacy through qualitative, quantitative, normative, and formative assessment structures such as, self-reported surveys, Software Recognition Test (SRT), Educational Activities Checklist (EAC), Recreational Experience Scale (RES) (see, Boechler et al., 2014); other formulations include code breaking, text-participating, text-using, and text-analyzing (see, Hinrichsen & Coombs, 2013) and operational digital literacy, usage digital literacy, communication and interaction digital literacy, and creation digital literacy (see Lee, 2014). The strategic integration of these techniques in curricular mapping remain vital as also properly training and upskilling teachers who ultimately impart classroom knowledge.

Another important aspect worth considering is digital literacy is not just an educational construct; it must also be fundamentally approached as a “social fairness issue” (Seale, 2009). The viewpoint generates awareness about digital divide and ethnocentric biases— two critical concepts surrounding the social aspect of digital literacy. In the prevailing circumstances social, political, and commercial activities are increasingly structured on ICTs and therefore for population with low digital literacy competence are at a risk of further marginalization. This divide or gap can potentially disengage individual from active citizenship, creating practical barriers for activities like accessing health and government information, public service information, engaging through social media, learning in mediated environments such as Massive Open Online Courses (MOOCs). In this connection, digital literacy education or DLE has significant implications in addressing the issue of digital divide. The primary goal of DLE is to “support learners’ knowledge and skill construction process through education and practices to enhance their digital literacy” (Lee, 2014). DLE aims to incorporate the social learning paradigm in life situations.

As indicated earlier, each society shapes and constructs definition of digital literacy according to its own social environment. However, many societies consider that other cultures must imitate their patterns of appropriation of digital technologies as “best practices” (Thatcher, 2010, p. 170)—a symptom of ethnocentric oversight. Digital literacy perceptions in global societies are influenced by numerous differentials including infrastructure, regulations, access, community participation, schools versus adult education, and individualism versus collectivism. It would therefore be a gross mistake to assume a universal approach. Consequently, effective measures can be developed to prevent ethnocentric biases in cross-cultural communications. According to Thatcher, one must be sensitized to the need to understand the rhetorical nature of the digital medium itself, to configure the characteristics of the medium to individual purpose, demands, and constraints, to assess the situation in the target culture, and finally to align to communication strategies to the expectations of target culture (p.169). This provides a functional framework that can negotiate the differences across disparate cultural configurations.

FUTURE RESEARCH DIRECTIONS

Current research in digital literacy reveals a solid direction toward developing a working definition of digital literacy and creating assessment tools for educational training. While establishing some type of functional metrics is important, it is equally important to build a corpus of scholarship addressing global discourse communities. Most research currently is confined to micro aspects of digital literacy, focusing mainly on theoretical constructs sometimes discounting the fact that in an information economy the scale of operation is not just regional or national but is global as well. Therefore, given the digital literacy landscape of

shared creativity and involvement in networked activities, it is time that conversations focused on exploring differences and trends between the west and the east, between the developed and the developing nations. Additionally, studies should refine the understanding of digital divide itself since most research on the digital divide tends to make a broad generalization using “multivariate analyses of several individual properties and aggregating them to produce properties of collectives” to support explanation (van Dijk 10). Generally, most approaches lack in conceptual clarity on one hand, and the idea of localization of use on the other. For example, in the west digital divide is defined in terms of use whereas in most other places it is still a matter of access to digital technologies. They also ignore or gloss over cultural factors and focus more on the overall use of technologies and their characteristics. Thus a repurposing of outcomes are warranted to take into consideration the more nuanced elements of digital literacy studies.

CONCLUSION

Digital literacy is multi-dimensional and no single context, culture or society has patent over its definition. Both conservative (skill) and skeptical (knowledge) orientations of digital literacy are still emerging, or at best tentative hypotheses and therefore extensive analyses are warranted before utilizing them as conclusive models. Knowledge paradigm enables individual agency by referencing one’s situation unlike the skill model where the user adopts a top-down task orientated structure. Digital literacy is indeed a crucial “life skill” whose salience cannot be overestimated as society transitions from essentially a linear to a hyper-linear mode of information processing. The digital literacy arc has shifted from its original focus on computers to technologies and to finally the idea of human agency.

KEY TERMS AND DEFINITIONS

Digital Divide: Disparities among individuals, generations, societies, and cultures resulting from unequal access to and use of computer and Internet technologies and digital infrastructures. Besides suggesting a physical quantity of presence or absence of technologies within a context, the divide implies a difference in quality of use of digital technologies within the same context.

Digital Native: A post-millennial term describing individuals who are part of the digital age from birth.

Hyperliteracy: A systematic process of finding, linking, and retrieving information by developing both critical and functional knowledge of the non-sequential structure of the Web. The primary focus is on understanding the structure of the Web

as providing freedom of organizing information by means of linking of ideas in a nonlinear way.

Information Literacy: A set of competencies associated with identifying the need for information, locating appropriate information, evaluating information, and utilizing information to participate effectively in cultural and social contexts. Recognized as a lifelong process of self-directed learning, information literacy underlies the role of informed citizenship through a proper understanding and use of digital technologies for fulfilling academic, professional, and personal goals.

Reproduction Literacy: Abilities to recreate and repurpose existing digital contents including text, sound, images, graphics, and videos into a new format using digital production capabilities.

Digital Literacy for the 21st Century

D**Hiller A. Spires***North Carolina State University, USA***Casey Medlock Paul***North Carolina State University, USA***Shea N. Kerkhoff***North Carolina State University, USA*

INTRODUCTION

In the past few decades, technology has spanned the globe, connected people in a whole new way. As a result, citizens of all countries have not only had to learn to use new technology, but also learn how to interact with one another. Skills that comprise these abilities have been combined under the term “digital literacy.” The purpose of this chapter is to (a) define digital literacy and its changing nature, (b) discuss implications of digital literacy on contemporary schooling, (c) demonstrate the impact of digital literacy on digital citizenship, and (d) analyze the implications of digital literacy on educational equity.

BACKGROUND

Almost two decades ago, Gilster (1997) defined digital literacy as the “ability to understand and use information in multiple formats from a wide range of sources when it is presented via computers” (p. 1). At this time, the Internet was in its infant stages. More than a decade later with Internet usage in full swing, Fieldhouse and Nicholas (2008) asserted that terms like *literacy* and *fluency* can be used to describe how users find and evaluate information within digital environments. Digital literacy involves any number of digital reading and writing techniques across multiple media forms, including: words, texts, visual displays,

motion graphics, audio, video, and multimodal forms. In the same way that literate individuals can negotiate print text through the processes of reading and writing, literate users of technology are able to consume and produce digital compositions. There are many cognitive processes at work, along a continuum from *consumption* to *production* when a reader is immersed with digital content. The digital context is challenging for all readers due to the fluid nature of the Web and the demand for critical judgments (Spires & Estes, 2002) as the reader makes decisions about how to locate information as well how to discern the reliability and credibility of that same information.

WHAT IS DIGITAL LITERACY?

Spires and Bartlett (2012) have divided the various intellectual processes associated with digital literacy into three categories: (a) locating and consuming digital content, (b) creating digital content, and (c) communicating digital content (see Figure 1). Learners must develop evaluative dispositions as they navigate digital content. A discerning mindset is essential in order to interact with online resources with accuracy. Without critical evaluation, the learner may easily be directed by the technology rather than the learner directing the inquiry.

DOI: 10.4018/978-1-5225-2255-3.ch194

Figure 1. Digital literacy practices involve the ability to locate and consume, create, and communicate digital content, while simultaneously employing a process of critical evaluation
Adapted from Spires & Bartlett (2012)

Locating and Consuming Digital Content

It is essential to develop the skills to locate, comprehend and consume digital content on the Web. Central to being effective with the Web is strategically searching for information and evaluating its accuracy and relevancy (Leu et al., 2008). There is consensus that effective Web search skills must be developed for educational success in a digital society, and instruments such as The Teaching Internet Comprehension to Adolescents (TICA) checklist can ensure that students have the necessary prerequisite Web search skills (Leu et al., 2008). However, more challenging is how to incorporate the effective teaching and development of Web search skills in the classroom (Moraveji et al., 2011). Nevertheless, some important skills are considered necessary for locating and using digital content: domain knowledge, a working knowledge of how to use search engines, basic literacy skills, and a general knowledge of resources available on the Web (Moraveji et al., 2011). In addition to building on the ability to craft productive Web search terms, search lessons should involve direct modeling of the use of search techniques, differentiating between domain names, and querying sites for accuracy and transparency.

Creating Content

Digital content is easily created by teachers and students alike through multiple media and a variety of Web 2.0 tools. The implementation of digital content may be an important and effective method of enhancing teaching and learning (Bakkenes, Vermunt, & Wubbles, 2010), enabling teachers to embrace the 21st century skills that students are expected to master. Digital resources can also free up teachers, allowing them to spend more time facilitating student learning and less time lecturing. Allowing students to create and consume digital content in the classroom may increase engagement while also encouraging the development of skills needed for a technological society. For example, students can create video content with easy-to-use video editors such as *Animoto*, *WeVideo*, and *Powtoon*, just to name a few. Because there is a low bar for technical expertise, students can spend more time on the quality of the content rather than learning the process of a new tool. An added benefit is that the products look polished and professional. Although the creation of digital content is becoming increasingly simple, personalization of learning will require teachers to locate and utilize a variety of digital resources to meet the needs of every learner. Personalization will also

put a heavier emphasis on asking students to show mastery of learning by producing digital content. This generative process requires more time from teachers in terms of designing appropriate rubrics for performance-based learning.

Communicating Digital Content

Digital content must be communicated effectively in order to be a useful educational medium. Using social networking sites like *Facebook*, *Twitter*, and *Instagram* requires users to understand and manipulate information in multiple formats. Web 2.0 tools are social, participatory, collaborative, easy to use, and facilitate the creation of online communities. Being able to communicate digital content using mobile devices such as cellphones and tablets provides convenience and immediacy to the communication process for teachers and students. Additionally, it provides access to an infinite set of people and digital content resources globally to enrich the learning experience. This type of communication affords the possibilities of more customization and personalization for individual learners' interests and needs, which has the potential to increase student engagement in academic learning.

A popular type of digital communication is the act of curating. The capacity to curate at a sophisticated level, both in terms of content and visual appeal, is quickly becoming a necessity for educators who engage in online teaching and learning (Thompson, 2015). The word curate comes from the Latin root *Curare*, or "to cure," and historically has meant "to preserve" (Mihailidis & Cohen, 2013). As students learn to be creators and curators of digital content, there is some evidence that it contributes to their ability to be critical readers of digital texts (O'Byrne, 2012). The word curate derives from the Latin root *Curare*, or 'to cure.' To curate, historically, has meant to take charge of or organize, to pull together, sift through, select for presentation, to heal and *to preserve*. Within digital spaces, organizing and preserving online content is the purview of the individual (Mihailidis

& Cohen, 2013). This online communication trend has created a need to understand how individuals select, sort, synthesize and display content within these spaces.

The Changing Nature of Digital Literacy and Learners

Contemporary education is permeated by the millennial generation, also referred to as Generation Y and the Net Generation. This group is defined as those individuals who were born between the early to mid-1980s and the early to mid-2000s, possessing the following traits: confident, team oriented, conventional, pressured and achieving (Howe & Strauss, 2000). This generation, bigger than previous generations, is entering the workforce and contributing to a shift in our society (Winograd & Hais, 2011). This generation is immersed in a world of multimodality, or how individuals make meaning with different modes, such as print, video, speech, music, or gesture. At the heart of multimodality, is semiotics, which is the study of signs (Kress & Van Leeuwen, 1996). As society has shifted from written to visual texts in contemporary culture, more demand has been placed on teachers to learn how to make instructional changes that take these shifts into account. Leu and his colleagues (Leu et al., 2015) used the term *deictic* to refer to the changing nature of literacy, which is prompted by the constantly changing technologies within our society. By all accounts, these changes will continue to take place since the total number of Internet users is at over 3 billion worldwide and growing.

Digital Citizenship

As technology has spread across the globe, our world has become more connected than ever. This has created a global virtual world that all technology users inhabit, and as a result, technology users have had to learn how to become "digital citizens" (Isman & Canan Gungoren, 2014). Although there are various definitions of this term,

the definitions are similar; they express that first and foremost, a digital citizen must be able to use technology intelligently. Furthermore, one should understand cultural and societal issues as they relate to technology; as a result, digital citizens demonstrate various characteristics. For example, Isman and Canan Gungoren (2014) state:

[They] practice legal and ethical behavior; advocate and practice safe, legal, and responsible use of information and technology; exhibit a positive attitude toward using technology that supports collaboration, learning and productivity; demonstrate personal responsibility for lifelong learning; and exhibit leadership for digital citizenship. (p. 73)

In order to foster the development of these skills, various organizations have begun to develop models and programs designed to assist in educating people on digital citizenship. For example, ISTE published a model listing behaviors associated with digital citizenship (Brichacek, 2014). Such behaviors include “no stealing or damaging others’ digital work, identity or property;” “using digital tools to advance learning and keeping up with changing technologies;” “protecting personal information from forces that might cause harm;” and “equal digital rights and access for all” (Searson, Hancock, Soheil, & Shepherd, 2015, p. 731). Another non-profit organization, *iKeepSafe*, worked with Microsoft and AT&T to develop an online questionnaire that measures digital safety skills and attitudes in six areas, known as the BEaPRO index: balancing digital usage, practicing ethical digital usage, protecting personal information, maintaining healthy and safe relationships, building a positive reputation, and achieving online security (Searson, Hancock, Soheil, & Shepherd, 2015; *iKeepSafe*, 2015).

Still, there is much work to be done in developing global digital citizenship. The findings from *iKeepSafe*’s questionnaire indicated “although many individuals *want* to foster good digital citizenship practices, most have limited knowledge

about how to do so” (Searson, Hancock, Soheil, & Shepherd, 2015, p. 733, emphasis in original). These authors provide a list of recommendations and actions needed to help further global digital citizenship. They suggest that both national and local leadership organizations, such as public policy agencies, law enforcement, and industry leaders, work together in order to tackle the issue. Furthermore, they recommend that educational institutions begin to provide professional development for teachers in order to educate teachers as to how they can teach their students to be digital citizens. They also maintain that stakeholders must be held accountable for privacy and safety of community members, and reported incidents should inform digital citizenship education services and policy development.

Although digital citizenship is a fairly new concept, it is one that is highly important in our globalized, virtual world. It involves not only competent technology use, but also responsible and ethical use of the web. Digital citizenship is largely considered an aspect of digital literacy, and many organizations are working to understand how to include it in digital literacy education.

Digital Literacy and Educational Equity

The digital divide is a gap in access to or usage of ICTs between people, demographic groups, or countries (OECD, 2001). In other words, the global digital divide is one of access to the Internet and also one of users’ competence with ICTs. Access to ICTs continues to be divided within countries as well as among countries and is often associated with socioeconomic status. As of January 2015, only 42% of the world was active Internet users with Canada holding the highest percentage of 93% and India holding the lowest percentage of Internet users at 19% (Kemp, 2015). Access and usage are related in that lack of access leads to less practice digital literacy skills, whereas more access leads to more opportunities to practice.

Problems of access include cost of computers and subscriptions, broadband width of the Internet, and restrictedness of content (Tongia, 2005). Lack of access can be seen at the country-level, such as governments censoring content on the Internet and restricting what sources and what information citizens can obtain. Lack of access can also be seen at the demographic level when certain demographic groups are able to spend more time on the Internet than other groups. In the US, research has shown that students from underprivileged schools spent less time using ICTs even though the amount of computers and broadband width were similar across schools (Leu et al., 2015). One reason for this could be that digital literacy is not tested on government issued assessments tied to funding; therefore, time is spent on what is tested in order to score higher on the assessments and receive needed funding (Leu et al., 2015). This phenomenon has implications for future K-12 assessments.

SOLUTIONS AND RECOMMENDATIONS

Digital Literacy and the Impact on Contemporary Schooling

As technology has become more integral to students' lives, there has been an ever-increasing digital "home-school divide" (Honan, 2006, p. 41); students are using technologies outside of school that are not available in school, while educators struggle to effectively use what technology they have in their classrooms (Henderson, 2011). There is still great debate on exactly how to integrate digital literacy instruction into traditional instruction, and many studies have been and are still being conducted in an attempt to understand how best to bridge the two together (Kervin, Verenikina, Jones, & Beath, 2013; Henderson, 2011; Walsh, 2010; 2008).

Nevertheless, there is little debate on the value of these skills; many countries have begun

to reform their education programs to include better digital education. Some countries even have standards and requirements for students to achieve digital literacy. In 2008, Australia began its Digital Education Revolution in order to equip schools, teachers, and students with the technology necessary to provide a quality digital education. England has Computing Programmes of Study (United Kingdom Dept. of Education, 2013) as part of its National Curriculum, with part of its stated goal that "pupils become digitally literate—able to use, and express themselves and develop their ideas through, information and communication technology—at a level suitable for the future workplace and as active participants in a digital world" (Purpose of Study section, para. 1). The International Society for Technology in Education (ISTE; 2007) has also developed standards for students, teachers, and administrators.

Not only has digital literacy changed educational standards, but it has also changed the content that must be taught in schools. Although today's students' are often considered "digital natives" (Prensky, 2001), they are not necessarily able to use these digital tools in a knowledgeable or critical way (Jones et al., 2010). Students therefore must be taught such skills and how to use technology effectively (Leu et al., 2015), including evaluating and critically analyzing information.

Students must also be taught about cyber safety, "digital footprints," and how to be responsible online (Osborne & Connely, 2015). In fact, many educational programs are now including standards that foster the teaching of digital responsibilities, such as respecting copyright laws, using valid information, and following safe and ethical behaviors when online. (American Association of School Librarians, 2007; ISTE, 2007). Government organizations are also making sure such education is available to students. For example, Qatar's Ministry of Information and Communications Technology, known as ictQATAR (2015), works alongside teachers and parents to teach children Internet responsibility and safety.

Digital literacy has had—and is continuing to have—an impact on contemporary education. Information is readily available to students, and educators are working to teach adolescents how to use this information effectively, ethically, and responsibly. One organization, the Partnership for 21st Century Learning, was developed in order to help foster 21st century learning for students through collaborative partnerships. The 21st Century Learning Framework (Partnership for 21st Century Learning, 2009) has been used in the U.S. as well as other countries to support the inclusion of 21st century skills in education. Although educators are still trying to discover exactly how digital literacy fits into the classroom, it is clear that digital literacy has already greatly altered modern education.

FUTURE RESEARCH DIRECTIONS

Future research should focus on clarifying best practices for teaching students how to navigate digital environments effectively. Specifically, teachers need to know how to help students locate, create and communicate digital content in productive and ethical ways. Additionally, teachers need best practices for how to integrate game-based learning into their classrooms and support students as they navigate virtual spaces related to content learning. One emerging trend is Online Reading Comprehension Assessments (ORCA), in which students' capacity to conduct effective information searches is assessed in a controlled Web environment (Leu et al., 2015). Online and offline reading require different skills, so assessments must be sensitive to the distinctions.

CONCLUSION

In this chapter our aim was to provide a definition of digital literacy and how it is evolving, discuss the implications of digital literacy on contemporary schooling, demonstrate the impact of digital

literacy on digital citizenship, and analyze the implications of digital literacy on educational equity.

KEY TERMS AND DEFINITIONS

Digital Citizenship: The capacity to conduct oneself in a responsible and ethical manner within public digital environments.

Digital Content: Content that uses information and communication technologies.

Digital Curation: The capacity to select, sort, synthesize and display digital content.

Digital Divide: The gap and access to or usage of ICTs between people, demographic groups or countries.

Digital Footprint: An individual's profile that is depicted to others through the Web.

Digital Literacy: The ability to locate, create, and communicate digital content.

Online Reading Comprehension: The ability to locate reliable sources on the Internet and synthesize for multiple purposes.

Web 2.0 Tools: Technology tools that allow interactivity among users and digital content.

Digital Literacy in Theory and Practice

D**Heidi Julien***State University of New York at Buffalo, USA*

INTRODUCTION

The concept of digital literacy must be understood in the context of “literacies” writ broadly. Contemporary understandings of literacy have expanded the traditional definition that includes reading and writing (possibly also including numeracy and orality), to include interpretive and creative abilities or competencies across a range of texts, in written and other forms. Text, in its contemporary sense, would include the written word, whether rendered on paper or digitally, as well as film and multi-medias. Competencies with texts of any kind are culturally situated, and therefore to be literate is to have the ability to make meaning within particular social conditions (Hoechsmann & Poyntz, 2012). Thus, meaning-making competency for economically privileged youth in a Western urban setting will differ markedly from the meaning-making by adults in a traditional agricultural milieu half-way around the globe with little access to networked communications. In Western industrialized societies, social communication practices via digital means, including interpretation, production, and dissemination, are now commonplace; the degree to which people have the abilities required to participate in these practices can be considered “digital literacy.”

BACKGROUND

Digital literacy, from a pragmatic point of view, is the set of skills, knowledge and attitudes required to access digital information effectively, efficiently, and ethically. It includes knowing how to evaluate digital information, and how to use it in decision-making. This definition is

a useful one, but it is one among many. Jaeger, Bertot, Thompson, Katz, and DeCoster (2012), for example, suggest that “digital literacy encompasses the skills and abilities necessary for access once the technology is available, including a necessary understanding of the language and component hardware and software required to successfully navigate the technology” (p. 3). For Jaeger and colleagues, digital literacy expands notions of the digital divide (a continuing challenge, even in wealthy nations), to add the ability to use technology, in addition to having access to it. They note that “digital literacy” came into its own in the 1990s, and they give credit to Gilster (1997) for moving the concept beyond the lists of information-handling skills articulated by national library associations in various countries, and for emphasizing information understanding and use. For Jaeger et al. (2012), “information literacy” is a subset of digital literacy.

Another perspective is that information literacy is the broader concept, since “information” need not be digital in format. The concept of information literacy has usually emphasized the contextual nature of information seeking, as well as the importance of information quality (Koltay, 2011). For some (e.g., Hobbs, 2010), information creation is an important aspect of digital literacy; that additional aspect relates digital literacy to the term “media literacy” which is also a commonly used term. There is no doubt that conceptual confusion is evident in this area, in which ICT (Information and Communication Technologies) literacy, computer literacy, computational literacy, technological literacy, information literacy, information fluency, digital literacy, transliteracy, and media literacy overlap in their meanings, and are employed differently by different authors and

DOI: 10.4018/978-1-5225-2255-3.ch195

agencies. As noted above, related concepts include literacy (basic reading and writing) and visual literacy, in addition to metaliteracy (a reframing of information literacy that emphasizes participatory online environments (Mackey & Jacobson, 2011)). Bawden (2008) focuses on competencies, suggesting that digital literacy consists of competency in internet searching, hypertext navigation, knowledge assembly, and content evaluation. Koltay (2011) believes that these competencies include notions of critical thinking (a traditional conceptual foundation of information literacy), knowledge assembly (collecting quality information), as well as publishing and communicating information. A broad definition of digital literacy is offered by Martin (2006, p. 19):

Digital Literacy is the awareness, attitude and ability of individuals to appropriately use digital tools and facilities to identify, access, manage, integrate, evaluate, analyse and synthesize digital resources, construct new knowledge, create media expressions, and communicate with others, in the context of specific life situations, in order to enable constructive social action; and to reflect upon this process.

Bawden (2008) notes that,

Digital literacy touches on and includes many things that it does not claim to own. It encompasses the presentation of information, without subsuming creative writing and visualization. It encompasses the evaluation of information, without claiming systematic reviewing and meta-analysis as its own. It includes organization of information but lays no claim to the construction and operation of terminologies, taxonomies and thesauri. (p. 26)

Conceptual confusion is exacerbated since the preferred term of the European Commission (2007) is media literacy, with a particular focus on critical awareness of commercially-produced information (Koltay, 2011, p. 217). A specific

emphasis on discerning the perspectives, intent, and quality of commercial information is not generally the focus of digital literacy discussions in the United States, for example. UNESCO uses the term “media and information literacy,” and it focuses on the need to empower citizens with essential knowledge about the functions of media and information systems in democratic societies. Digital and media literacy is viewed as contributing to sustainable human development, participatory civic societies, sustainable world peace, freedom, democracy, good governance, and fostering of intercultural knowledge and mutual understanding. Such lofty goals place considerable intellectual, political, and practical burdens on a concept such as digital literacy. From the UNESCO perspective, media and information literacy is core to freedom of expression and information, empowering citizens to understand functions of media and other information providers, to enable critical evaluation of content, and to facilitate citizens to make informed decisions as users and producers of information and media content.

Karpati (2011), reflecting a UNESCO perspective, states that digital literacy includes “the use and production of digital media, information processing and retrieval, participation in social networks for creation and sharing of knowledge, and a wide range of professional computing skills” (p. 1), broadening the scope of this concept to include high-level technological competence. UNESCO is particularly focused on the relevance of digital literacy to enhance employability, and lifelong learning, with an obvious goal towards human economic and social development. For Karpati (2011), the most important aspects of digital literacy are “accessing, managing, evaluating, integrating, creating, and communicating information individually or collaboratively in a networked, computer supported, and web-based environment[s] for learning, working, or leisure” (p. 4). Karpati cites the UNESCO’s Annual World Report 2009, Information Society Policies (UNESCO, 2009), which focuses on the relevance of the digital divide, and digital literacy,

in developing nations. In these contexts, digital literacy is considered critical to development of basic literacy and to lifelong learning (Karpati, 2011, p. 6).

Hobbs (2010), writing in the U.S. context, also uses the term “digital and media literacy.” This term is defined very broadly to include the “full range of cognitive, emotional and social competencies that includes the use of texts, tools and technologies; the skills of critical thinking and analysis; the practice of message composition and creativity; the ability to engage in reflection and ethical thinking; as well as active participation through teamwork and collaboration” (p. 17). For Hobbs, what is particularly relevant is the capacity for digital and media literacy to empower people to critically analyze the agendas inherent in information sources, and to advocate for minority or marginalized points of view. She clearly takes a competency view of digital and media literacy, noting that the concept includes the following skills: the ability to access and share information using media and technology, the ability to critically analyze and evaluate information, the ability to create information in sophisticated ways, the ability to reflect on information and communication from an ethical perspective, and the ability to work individually or with others to share information in all contexts (personal, workplace, and at all community levels) (Hobbs, 2010, p. 19). Wohlsen (2014) reiterates the lack of a clear definition for digital literacy, but makes the point that information creation is an important element of the concept.

In the United States, digital literacy tends to be contextualized in terms of the ongoing digital divide, and so it is viewed as important for digital inclusion in communities (Institute of Museum and Library Services, 2012). Digital inclusion assumes the ability to appreciate the benefits of ICTs, and means that citizens are able to use ICTs to access educational, economic, and social opportunities. This concern for expansion of opportunity echoes that expressed by UNESCO. The American Library Association Digital Literacy

Task Force (2013) defines digital literacy as “the ability to use information and communication technologies to find, understand, evaluate, create, and communicate digital information, an ability that requires both cognitive and technical skills” (Digital Literacy Task Force, 2013, p. 2). This report expands the concept to include information stewardship, communication with others, civic participation, and democratic engagement. For the American Library Association, digital literacy is conceived in global terms, and its importance is underlined by tying digital literacy to its potential role in helping the U.S. compete in global economic, educational, and intellectual contexts. The educational link is also made between digital literacy and the Common Core State Standards Initiative for U.S. schools, which actually focuses on “media”. The Digital Literacy Task Force (2013) affirms the critical role of libraries in promoting digital literacy and in supporting programs which develop digital literacy, in partnership with other organizations and institutions.

DIGITAL LITERACY TRAINING

The importance of digital literacy is widely recognized internationally, and top-down efforts in many nations to encourage digital literacy were evident from the 1990s forward. For example, the New Zealand Computer Society has stated that digital literacy is “an essential life skill and right of every... citizen” (Bunker, 2010, p. 5). Further, the Society states that addressing ICT competence in the workforce could increase productivity by \$1.7 billion (in time saved); that ICT competence improves employment opportunities, overcomes isolation, builds confidence and leads to further learning; and, it recommends that national governments should take leadership roles in developing digital literacy among citizens. Digital literacy training initiatives around the world fall on a continuum: basic initiatives, which are the most common, focus on developing basic computing skills applied to everyday simple

tasks. A second level, found less often, focuses on using basic functionality of key applications (word processing, spreadsheets, presentation tools, email, web searching). At the third level, which is rarely found, the focus is on developing confident use of digital tools and facilities to identify, access, manage, integrate, evaluate, analyze, and synthesize digital resources; construct new knowledge; create media expressions; use the net for transactions; and, develop awareness of security issues. Most digital literacy initiatives are derived from centralized policies at national or regional levels, and are strategically linked with government objectives such as developing an information society, and bridging the digital divide. Therefore, centralized initiatives tend to focus on disadvantaged groups such as the elderly, disabled, or unemployed. Other digital literacy initiatives focus on related strategic goals, such as social cohesion, immigrant integration, supporting lifelong learning, and supporting optimal use of online government services. Usability and accessibility, as components of digital literacy, tend not to be emphasized. Often, digital literacy initiatives are partnerships between governments and other institutions. Non-governmental bodies partnering on such initiatives tend to be motivated by a desire to help disadvantaged groups, while private companies may well be motivated by perceived opportunities to grow their market share of products, such as broadband in rural areas, hardware or software purchase by the elderly or disabled, and improving workforce competencies (Shapiro, 2009).

A recent analysis of 470 digital literacy initiatives and survey data in the EU ("Digital Literacy European Commission Working Paper", n.d.) found that digital literacy programs have grown, especially for young people. In addition, the analysis determined that more efforts are required to develop digital literacy skills among older and disadvantaged groups, and that developing trust and confidence in digital transactions remains challenging. This report notes that investment in digital literacy programs have shown positive

outcomes, including expanding internet access and use, encouraging non-users or less-skilled users, and providing training based on user preferences for informal learning approaches and focusing on daily life activities and interests. The report concludes that there remains a significant proportion of the population that does not use the Internet, and that potential exists to focus on differences in quality of use.

In the United States, digital literacy is being supported by a number of organizations and agencies. An online portal, DigitalLiteracy.gov (<http://www.digitalliteracy.gov/>), provides resources to communities and organizations to support local digital literacy initiatives. Individuals can also access training resources on that portal to develop their own digital literacy skills. Digital literacy efforts in schools have been spurred by legislation. In the U.S., the No Child Left Behind Act and the related Enhancing Education Through Technology Act require technological literacy for all children, which enhances digital literacy efforts, especially for children from families without online access (American Library Association, 2012, para. 23). Also in the education context, UNESCO has been active in discussions about technology in education (*cf.* UNESCO's Grünwald Declaration on Media Education, 1982), has worked to develop international media education guidelines, and has developed a media and information literacy curriculum (American Library Association, 2012, para. 20). There is little question that digital literacy is important to education at all levels, and is especially relevant in inquiry-based learning. Many universities worldwide have incorporated digital literacy outcomes into strategic planning efforts, although the degree to which these outcomes are evident in their graduates remains uncertain.

There has been a significant growth in resources to support digital literacy learning, provided by a range of public and private organizations and partnerships. Examples include the Public Library Association's Digital Learn hub (<http://digitallearn.org/>), MediaSmarts in Canada (<http://mediasmarts.ca/>), the LinkAmerica's Founda-

tion Digital Literacy site (<http://www.ictliteracy.info/#>), Microsoft's Digital Literacy site (<https://www.microsoft.com/en-us/digitalliteracy/overview.aspx>) and Google's Digital Literacy and Citizenship Curriculum (<https://www.google.com/goodtoknow/web/curriculum/>). Some sites focus on internet safety for children and youth, such as the UK Safer Internet Centre (<http://www.saferinternet.org.uk/>). U.S. Digital Literacy (n.d.) is an example of a professional development resource designed by teachers for teachers. The site provides definitions and a multiplicity of learning opportunities for teachers who wish to learn about this topic.

CHALLENGES

Digital literacy is recognized as critical to positive health outcomes (of particular importance when so much health information is now obtained online), workforce development, and participative governance (since participatory citizenship is dependent upon relatively sophisticated information finding skills). Digital literacy goes beyond social networking, and increasingly, governments are delivering information and services online, and online only, which requires citizens to be at least minimally digitally literate in order to access that information. In addition, participation in the 'commons' and in 'civil society' depends on citizens' ability to find and evaluate information. Digital literacy is also recognized as an essential competency for job performance, since information gathering, manipulation, and application are key work tasks. Those without good digital literacy skills will be marginalized in private and public life, including employment. A recent report (Head, 2012) suggests that employers in the U.S. are not generally pleased with the digital literacy skill set exhibited by employees newly graduated from university. These young people rely on superficial information searches, lack the skills and perseverance to conduct sophisticated and in-depth information searches, and fail to bring

information from a variety of sources together in useful ways.

Of increasing concern is the growing recognition that digital literacy skills are not developed through experience alone. The key role for formal digital literacy training efforts is twofold: to ameliorate the digital divide, and to emphasize the role of critical analysis in communicative practice (Hoechsmann & Poyntz, 2012, 147). Effective and efficient information-finding skills take time and effort to learn. Information is organized in complex ways, and can be difficult to evaluate. There is growing consensus that, for most people, confidence in information skills exceeds actual skill level. Skills deficits are especially apparent for effective information finding skills and information evaluation skills. Many people do not understand the context of information—how or why it is produced, nor the purposes for which different types of information are made available. Thus, critical evaluation is difficult. Research shows that students entering post-secondary education typically are “surf savvy” but not “search savvy,” and many students, and people in general, do not understand how to evaluate the information they find (Nicholas et al., 2009). Authority is assessed within seconds by dipping and cross-checking across different sites and by relying on favored brands (e.g., Google). The speed of web searching indicates that little time is spent evaluating information for relevance, accuracy or authority. In addition, many people do not understand (or respect) ethical boundaries on using others' ideas and writing, relying on cut and paste techniques to bring disparate information together. It seems clear that there is significant potential for learning institutions at all levels to play important roles to expand the interpretive repertoires of their learners, and to develop a “questioning and reflective approach that recognizes the social and cultural implications of the technologies, institutions, and texts” (Hoechsmann & Poyntz, 2012, 149).

If many people with access to computers and networks remain digitally illiterate, how can this status quo be addressed? Presumably, digital

literacy skills can be learned from teachers in school; however, despite curricular mandates in many jurisdictions, and the presence of certified school librarians in some schools, we know that actual skills continue to be low (Julien & Barker, 2009; Gross & Latham, 2012). Teachers are not necessarily digital literate themselves, so it may be unrealistic to expect them to impart skills they do not yet possess. Teachers' classroom time also is limited, and digital literacy skills tend not to be tested. What is not tested is less likely to be emphasized. When parents are digitally literate, children may learn these skills, but many parents lack this knowledge to pass along. Often, opportunities to develop digital literacy skills exist at post-secondary educational institutions, but instruction is not systematic, may be very limited, and may not be done well (Julien, 2006). The same concerns apply to opportunities at public libraries and other community centers.

Other challenges to developing widespread digital literacy skills include unfounded beliefs about the relative skills and understandings of so-called "digital natives," and assumptions about the value of experience with ICTs without formal learning of skills. Competence with social media or quick Google searches does not necessarily translate into sophisticated information evaluation skills. Another challenge is assumptions about the capacity of libraries to play significant roles in developing citizens' digital literacy skills. Libraries often face severe resource challenges, library administrators may place relatively little emphasis on client training in digital literacy, library customers may lack confidence in the potential for librarians to contribute to digital literacy training, and librarians may be poorly prepared for instructional work (Julien & Hoffman, 2008). In most jurisdictions there is also limited coordination between school teachers and librarians in public libraries and academic libraries, as well as insufficient numbers of teacher-librarians in schools; in many jurisdictions globally, librarian positions in schools have been eliminated entirely. Where potential exists for librarians across contexts to work together to develop community capacity in

digital literacy, actual cooperation or coordination is rare.

FUTURE RESEARCH DIRECTIONS

Research in digital literacy focuses largely on the ways in which it can be further developed among specific populations or in specific contexts, and there remains substantial work to do in this area. For instance, there are nuances related to the learning and expression of digital literacy that will differ between adults and children, and between disparate cultural, educational, and workplace settings. Certainly a focus on outcomes of digital literacy education is also warranted, and should be a significant concern for societies globally. In addition, the digital literacy landscape will evolve with changes in information technologies, and these changes will merit research attention.

CONCLUSION

Despite these challenges, the list of potential benefits arising from individual and community digital literacy is lengthy, and the value of digital literacy is significant. Some perspectives and agendas focus on overtly political outcomes of widespread digital literacy, including enhancing democracy, world peace, and empowering previously marginalized groups politically and socially. Digital literacy certainly has the potential to contribute to far-reaching and important personal and societal consequences. Thus, increasing focus on development of digital literacy, however defined, should be a policy priority for all sectors.

KEY TERMS AND DEFINITIONS

Digital Divide: Inequalities between people with access to digital technologies and those without such access. Access may include access to hardware, software, internet connections, and possessing the skill set needed to make use of these technologies.

Digital Literacy: The set of skills, knowledge and attitudes required to access, create, use, and evaluate digital information effectively, efficiently, and ethically.

Digital Native: A person who has interacted with digital technology for most of his or her life.

Encouraging Digital Literacy and ICT Competency in the Information Age

D**Kijpokin Kasemsap***Suan Sunandha Rajabhat University, Thailand*

INTRODUCTION

The growing prominence of the Internet as educational tool requires research regarding learners' digital literacy (Greene, Yu, & Copeland, 2014). Nowadays, students autonomously acquire their digital literacy and are adept at using various ICT tools to enrich their daily leisure lives (Ting, 2015). Digital literacy includes the ability to search for information and to integrate that information while monitoring progress toward achieving educational goals (Bråten, Britt, Strømsø, & Rouet, 2011). Digital natives often engage themselves in the use of ICT tools and in accessing, creating, and sharing both text and videos on the Web 2.0 (Junco, 2012). The ability of digital natives to embrace ICT suggests that they possess a certain level of digital literacy (Ng, 2012).

Competency refers to the ability resulting from individual's knowledge, skills, characteristics, and attitude in executing work to achieve success (Malinina, 2015). ICT plays a critical role in enhancing the quality of education (Vitanova, Atanasova-Pachemska, Iliev, & Pachemska, 2015). Within the context of 21st century skills, the importance of being digitally competent is reflected in the international and national policies for the educational ICT utilization (Kozma, 2008). These policies for educational ICT utilization have introduced ICT competency in the national and school curricula (Aesaert, Vanderlinde, Tondeur, & van Braak, 2013), such as the integration of ICT competences in the educational curricula. ICT competency standards practically define the achievement expectations for students (Thomas & Knezek, 2008).

This article aims to bridge the gap in the literature on the thorough literature consolidation of digital literacy and ICT competency. The extensive literatures of digital literacy and ICT competency provide a contribution to practitioners and researchers in order to maximize the impact of digital literacy and ICT competency in the information age.

BACKGROUND

Technology Acceptance Model (TAM), such as Unified Theory of Acceptance Use of Technology (UTAUT), explains the degree of acceptance of the utilization of information technology (IT) toward adopting the technological infrastructure (Nchunge, Sakwa, & Mwangi, 2013). TAM helps managers and decision makers to evaluate the success of the acceptance of technology to the organization, and motivate users to accept the systems. UTAUT identifies four key factors (i.e., performance expectancy, effort expectancy, social influence, and facilitating conditions) and four moderators (i.e., age, gender, experience, and voluntariness) concerning behavioral intention toward utilizing technology in organizational contexts (Venkatesh, Thong, & Xu, 2016).

Digital literacy refers to the variety of literacies associated with the use of new technologies (Mohammadyari & Singh, 2015). Digital literacy is a fundamental life skill in today's knowledge economy and information society (Bawden, 2001). Digital literacy constitutes new practices rather than new instances of established practices (Simpson & Obdalova, 2014). Proficiency in

digital literacy refers to the ability to read and write using online sources, and includes the ability to select sources relevant to the task, synthesize information into a coherent message, and communicate the message with an audience (Bulger, Mayer, & Metzger, 2014). Appel (2012) defined digital literacy as the ability to find and analyze information by using computers.

Digital literacy is a broad concept encompassing the different aspects, and its development follows a continuum from the acquisition of instrumental skills to that of strategic competence and cognitive skills (Calvani, Fini, Ranieri, & Picci, 2012). Digital literacy is the awareness, attitude and ability of individuals to appropriately utilize the digital tools to identify the digital resources, construct the new knowledge, create the media expressions, and communicate with others (Martin, 2005). Hatlevik and Christophersen (2013) used the term digital competence to describe the acquisition and processing of digital information and the ability to produce the digital information.

Competency is made up of knowledge, skills, and attitude (Malinina, 2015). ICT competency is considered as the educational outcomes (Thomas & Knezek, 2008). ICT competency refers to knowledge, skills, and ability to take advantage of ICT for the purpose of gathering, processing, and presenting the information in support of activities among different groups of people (Albirini, 2006). Traditional methods of teaching ICT are not an effective way for learners to acquire ICT competencies or to gain more positive ICT perceptions (Goktas, Yildirim, & Yildirim, 2008). Instead, learners should interact with new information in ways that enable the active inquiry to promote the useful learning (Daugherty, 2005). To gain ICT competency, learners should be given opportunities to create their own meaning-making processes in order to establish their own knowledge (Goktas & Demirel, 2012).

ADVANCED ISSUES OF DIGITAL LITERACY AND ICT COMPETENCY

This section emphasizes the overview of digital literacy and ICT competency, the encouragement of digital literacy in the information age, and the encouragement of ICT competency in the information age.

Overview of Digital Literacy

Twenty-first century learning skills require the ability to use the Internet technology (Greene et al., 2014). The prominent role the Internet plays in home and classroom lives demands careful attention to its link to student knowledge gains (Greene et al., 2014). The Internet, as a text, consists of multiple print, images, videos, and interactive simulations, all used to communicate with the subsequent effects upon cognition (Collins & Halverson, 2009). While it is important to consider how the Internet utilization affects the students' different cognitive processes (Reinking, 2005), it is important to consider how different cognitive processes influence how students engage with the Internet (Strømsø & Bråten, 2010).

Digital literacy is an important determinant to consider as the number of electronic learning (e-learning) tools has expanded to incorporate the Web 2.0 innovations, such as blogs, podcasts, and wikis (Mohammadyari & Singh, 2015). Digital literacy is a significant determinant of attitudes toward computer-assisted language learning (Oz, Demirezen, & Pourfeiz, 2015). Ullrich et al. (2008) stated that the rapid spread of these tools has meant that individuals often have had to train themselves in how to use these tools. Individuals with a high level of digital literacy have been better able to leverage these new tools to self-manage their training and execute their continuing education activities in an informal setting, toward reducing the interruption to their working lives (Hargittai, 2010).

Besides the technical awareness, digital literacy includes the social and cognitive skills required in the digital environment (Huerta & Sandoval-Almazan, 2007). Eshet-Alkalai (2004) stated that digital literacy includes five skills: photo-visual skills, reproduction skills, branching skills, information skills, and socio-emotional skills. The key motivator behind the growing use of these tools has been the ability to quickly incorporate the material about new developments in a field into the training material, which is important for the fields, which are affected by technology-related issues, such as privacy, security, and standards (Arbaugh & Duray, 2002).

Overview of ICT Competency

ICT competency refers to the learning-process oriented competence used in the complex, authentic, and unpredictable situations, and is underpinned by the technical and application ICT knowledge and skills (Aesaert et al., 2013). Markauskaite (2007) indicated that ICT competency refers to the interactive use of cognitive capabilities and technical capabilities in order to accomplish the cognitive information and ICT-based tasks. Digital information processing and digital communication are recognized as ICT competencies to be measured because these are identified as two themes in the national and international ICT frameworks (Voogt & Roblin, 2012).

Application of ICT initiates the new opportunities in arranging the educational environment (Malinina, 2015). Various types of professional development programs concerning ICT implementation have been organized for in-service teachers toward upgrading ICT competency among teachers and bringing the change to their teaching practices, such as integrating ICT in classroom (Borko, 2004). In order to produce the effective learning through ICT utilization, students should develop the technological competencies, and teachers should develop the teaching, learning, and technological competencies (Pineida, 2011).

Encouragement of Digital Literacy in the Information Age

Digital literacy refers to the skills and knowledge in using computers in a hypermedia environment (Ting, 2015). Digital literacy refers to the cognitive processes that individuals partake in during the utilization of computer-based, multimodal information (Mayer, 2005). Digital literacy, as a complex frame of specific diversified capabilities, represents an actual phenomenon within the social matrix, sourced in the developing potential of the digital technology and the required information literacy (Javorský & Horváth, 2014). Institutions need to place greater value on digital literacy, and better prepare their students and their own organizational processes to thrive in an age of digital knowledge practices (Littlejohn, Beetham, & McGill, 2012).

In terms of the ways in which digital literacy is acquired, adolescents, in particular, engage in a broad range of computerized activities, including doing homework, searching and gathering information on the Internet, using social media platforms to communicate with friends, watching videos on YouTube, and playing educational video games (Appel, 2012). Educational computer games can motivate students to develop the basic competencies and encourage challenging themselves to be better and learn the additional knowledge related to the important tasks (Kasemsap, 2017a). Social media tools are open to anyone, whereas reaching the traditional media often requires a lot of money and a good network of media industry contacts (Kasemsap, 2016a). The use of social media has created the highly effective communication platforms where any user, virtually anywhere in the world, can freely create the content and disseminate this information in real time to a global audience (Kasemsap, 2017b).

For ICT tools, especially for those intended for entertainment purposes, students are often more skilled and adept at using them than their teachers, such as when the ICT tools are used to edit videos and upload them to Facebook or Youtube (Gu, Zhu,

& Guo, 2013). Students autonomously learn the instrumental skills and knowledge of computers and the Internet outside formal education (Eynon & Malmberg, 2011). Because students are raised in such the networked digital environment, their patterns of thinking and communication, notions of learning, needs for control, and even their personal and social values have been shaped by this networked digital environment (Gu et al., 2013). There has been an increasing interest in the ways that young people are using the Internet and other new technologies in their everyday lives and how such use may enhance the informal and formal learning opportunities (Lim, Zhao, Tondeur, Chai, & Tsai, 2013).

The advent of a knowledge-based society, where economic wealth depends on individuals' ability to deal with the abundance of information and to adapt to an ever-changing working environment, makes digital literacy an obvious concept for examining the individual adoption of IT (Mohammadyari & Singh, 2015). Digital literacy empowers individuals to communicate with others, work more effectively, and increase the individual's productivity, particularly with those who have the same skills and proficiency levels (Martin, 2008). Digital literacy reduces the individuals' inclination to unfavorably regard their achievements (Eastin & LaRose, 2000), which should make them more confident about their expected performance.

Self-regulated learning (Winne & Hadwin, 2008) skills, inclusive of making effective plans, and controlling these plans, as well as the strategies used to enact those plans and the learning that results (Azevedo & Jacobson, 2008), are likely to be the critical components of digital literacy. Some researchers have equated digital literacy with search literacy, or searching for information online and information literacy (Hockley, 2012). For example, cognitive overload and disorientation are two primary reasons why students struggle to effectively search the Internet (Gerjets, Scheiter, & Schuh, 2008).

Encouragement of ICT Competency in the Information Age

Regarding ICT competency encouragement, blogs can be utilized as an online learning tool to provide students with access to the significant information, to enlarge the students' understanding of specific issues, and to direct students to investigate the additional materials (Luehmann, 2008). Using blogs in ICT courses can increase the students' perceived technological competencies, while promoting their dynamic engagement (Goktas & Demirel, 2012). Blogs can encourage engagement in the educational activities and involve the interactive communities of learners (Goktas & Demirel, 2012).

Individuals who are regarded as having ICT competency must be able to produce necessary documents, find out solutions to problems, and choose proper ICT tools for problem solving and effective work (Malinina, 2015). Creating and maintaining a weblog using the created blogging software is an easy process, and an instructor can use this learning format to publish the course materials and post the announcements, presentations, timetables, and other information on the Web toward increasing the students' ICT competency (Wassell & Crouch, 2008).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of digital literacy and ICT competency will provide the potential opportunities for future research. Human capital is the collective skills, knowledge, or other intangible assets of individuals that can be used to create the economic value for the individuals, their employers, or their community (Kasemsap, 2016b). Continuing professional development is the training and education that continues throughout an individual's career in order to improve the skills and knowledge (Kasemsap, 2017c). An examination of linkages

among digital literacy, ICT competency, human capital, and continuing professional development in the workplace would seem to be viable for future research efforts.

CONCLUSION

This article highlighted the overview of digital literacy and ICT competency, the encouragement of digital literacy in the information age, and the encouragement of ICT competency in the information age. Ability to use technology is a critical prerequisite for understanding information communicated through that technology. Digital literacy and ICT competency are the abilities to locate, organize, understand, evaluate, and analyze information using computers and digital technology. Digital literacy and ICT competency have led to the great increases in information that can be conveniently and quickly accessed and effectively facilitate the collaboration and sharing of knowledge. While employability is an obvious driver, developing learners who can learn in the digital society is the significant role for universities and colleges.

Digital literacy and ICT competency look beyond functional IT skills to describe a richer set of digital behaviors, practices, and identities. Digital literacy and ICT competency are a set of academic practices supported by diverse learning methods, such as electronic learning and game-based learning. Encouraging discussion about supporting students with digital skills and the associated impact on the teaching staff roles helps broaden the awareness of both digital literacy and ICT competency across educational institutions. The staff and students involved do not need to be technology experts; effective communication skills, educational flexibility, and an eagerness to learn are crucial toward encouraging both digital literacy and ICT competency.

Benefits of digital literacy and ICT competency include the enhanced capacity to remain abreast of technology developments and effectively

utilize technology to increase productivity and competitiveness in all sectors of the economy and to develop the innovative networks, products, and services for the rapidly growing ICT marketplace. The encouragement of digital literacy and ICT competency is essential for modern organizations that seek to serve suppliers and customers, increase business performance, strengthen competitiveness, and achieve regular prosperity in the information age. Thus, it is required for modern organizations to encourage their digital literacy and ICT competency and develop a strategic plan to regularly investigate their practical improvements toward satisfying customer requirements. Encouraging digital literacy and ICT competency has the potential to enhance organizational performance and achieve strategic goals in the information age.

KEY TERMS AND DEFINITIONS

Blog: The website, similar to an online journal, that includes chronological entries made by individuals.

Competency: The important skill that is needed to do a job.

Information Technology: The set of tools, processes, and associated equipment employed to collect, process, and present the information.

Internet: The worldwide computer network that provides information on very many subjects and enables users to exchange messages.

Knowledge: The state of knowing about or being familiar with something.

Learning: The activity of obtaining knowledge.

Literacy: The knowledge of the particular subject, or the particular type of knowledge.

Technology: The use of scientific knowledge to solve practical problems, especially in industry and commerce.

Information Needs of Users in the Tech Savvy Environment and the Influencing Factors

Mudasir Khazer Rather
University of Kashmir, India

Shabir Ahmad Ganaie
University of Kashmir, India

INTRODUCTION

Information environment is enough rich, characterized by a growth in information sources as well as providers, a variety of approaches and techniques for accessing information, and a redundancy of content from multiple sources. In this “overloaded” information environment, many information users tend to experience a sense of insufficiency in locating the precise information which leads to anxiety. In this complex information environment, understanding the way individuals choose to satisfy their information needs takes on new urgency. Insight into information seeking can be gained by understanding how users seek information sources and how they locate the desired information to meet their needs (Chandra, Lynn, Lawrence & Lillie, 2007). The concept of information needs was coined by an American information scientist Robert S. Taylor in his article “The Process of Asking Questions” published in *American Documentation* (Now is *Journal of the American Society of Information Science and Technology*). There are many definitions of information need. According to Case (2012) information need is a recognition that your knowledge is inadequate to satisfy a goal that you have. He explains that “having information” is not the same as “being informed.” Information need is one of the cognitive needs of humanity. Information need determines information-seeking behavior and these concepts harmonize one another.

Information need is influenced by a number of factors. It is revealed from the literature that ‘information scattered in too many sources’ and that too in multi-formats is the problem often faced by users. For fulfilling the information needs, users access different sources of information Sources. Scientists, engineers and technologists in general use encyclopedias, handbooks, textbooks, periodicals, abstracts, indexes, standards, patents, etc. for their research and development works. He showed that information needs of scientists, engineers and technologists are equally based on their knowledge about those sources of information and accessibility of these information sources (Gayatri, 2006). Post Graduate students and Research Scholars mostly use journals, library books and textbooks for completing their course work (Fidzani, 1998). The information needs of teachers were found to be mostly related to guidance on administrative procedures, having lesson plans ready, mechanisms for evidencing work, etc (Williams, 2005). Further, information needs of the General people are found to be varied. The areas in which they needed information are diverse. These range from the information needs of the farmers, to that of the petty traders, artisans, blacksmiths, weavers, painters, fishermen, postmasters, labors, adult learners etc (Kadli & Kumbar, 2011). This chapter provides an overview of information needs of users, their types and also the various factors influencing the information needs of users in the digital age.

DOI: 10.4018/978-1-5225-2255-3.ch197

BACKGROUND

Developments in the present tech savvy information world have been witnessed only since when the communication of information has been speedy and rapid. Information is the fundamental unit of communication. Communication is the transmission of information in the form of signs and symbols which gave birth to the concept of data. Data is a codified and communicable symbolic representation of entities, properties and their states. They have content (representation) and form (record) that allow storage, retrieval, transfer, aggregation, and analysis. Data can turn into information if they are put into a context and given meaning. Information is a string of signs and symbols that can be interpreted as a message. It can be transmitted in the form of signals. Information is any sort of event that changes the state of a dynamic system. The meaning of this concept varies in various contexts. Information is closely correlated to notion of data, message, knowledge, wisdom, meaning understanding, perception, communication etc (Silvio, 2006). According to some authors, data are understood to be symbols that have not yet been interpreted, information is data with meaning, and knowledge is what facilitates people to allocate meaning and thereby generate information. Data have generally been taken as simple facts that can be structured to develop information. Information is the English word which is apparently derived from the Latin stem (*informatio*): this noun is derived from the verb “informare” (to inform) in the sense of “to give form to the mind”, “to discipline”, “instruct”, “teach”. *Inform* itself comes from the Latin verb *informare*, which means to give form, or to form an idea of. Furthermore, Latin itself already contained the word *information* meaning concept or idea, but the extent to which this may have influenced the development of the word *information* in English is not clear (Wikipedia, 2013).

A number of authors have given their views and opinions regarding the concept of information. According to Cawkell, (2003), “Information is an assemblage of data in a comprehensible form

capable of communication and use”. While as Martin (1995) believes Information is that which adds to or modifies knowledge structure. Singh (2007) reveals that Information seems to be everywhere. Information is being encoded in the genes, disseminated by media of communication, exchanged in conversation [discussion], contained in all sorts of things, libraries are overflowing with it, institutions are bogged down by it, and people are overloaded with it, still no one seems to know exactly what information is. Adeoti-Adekeye (1997) explains that there are three major fields of information which have traditionally been divided and separated. The first is the literature field of libraries and archives, where information has been put into recorded form. The second is the document field of information centers and record centers, where information has been collected and organized but perhaps not seriously evaluated in the same sense as in the literature field. The third information field is the data field of computers, telecommunications and automated information systems where the information is often numerical or structured.

Data vs. Information

Data refers to raw, unevaluated facts, figures, symbols, objects, events, etc. Data may be a collection of facts lying in storage, like a telephone directory or census records.

Information is data that have been put into a meaningful and useful context and communicated to a recipient who uses it to make decisions. Information involves the communication and reception of intelligence or knowledge. It appraises and notifies surprises and stimulates, reduces uncertainty, reveals additional alternatives or helps eliminate irrelevant or poor ones, and influences individuals and stimulates them to action. An element of data may constitute information in a specific context; for example, when you want to contact your friend, his or her telephone number is a piece of information; otherwise, it is just one element of data in the telephone directory (Babu, Singh & Sachdeva, 2013).

Knowledge is the outcome of information and has been defined in a number of ways. Al-Salti and Hackney, (2011) defines knowledge as “a product of human reflection and experience”. Moreover, it has been considered as a powerful tool to develop better decision making and innovation. Recently, many researchers have stressed that knowledge is an important factor to gain and sustain a competitive advantage. There are two main dimensions of knowledge: explicit and tacit. Explicit knowledge is transmittable knowledge that exists in symbolic or written form and stored in readily accessible media such as manuals, documentations, procedures and program codes. Tacit knowledge, on the other hand, is knowledge that resides in the minds of people but difficult, or even in some cases impossible, to be expressed in verbal, symbolic and written form such as insights, expertise and experience. Such knowledge cannot be transferred through a written document, and yet it is very important in the organization. The above discussion reveals that Knowledge is the outcome of information which itself is considered as the meaningful data.

Data, Information, Knowledge, and Wisdom

Many authors and researchers around the globe have co-related the concept of data, information with knowledge and wisdom. According to Tuomi (2000), when the information is interpreted or put into context, or when meaning is added to it, it is converted into knowledge. There are a number of variations of this widely accepted theme. The general idea is that data is somewhat less than information and that information is less than that of knowledge. Furthermore, it is understood that data is necessary for the creation of information and knowledge emerges only when we have knowledge (Figure 1).

Figure 1 is in accordance with what Singh, (2007) divulges that there is an established hierarchical liaison between data, information and knowledge. Data can be defined easily as “raw”

Figure 1. Relation b/w data, information, knowledge, and wisdom

facts, which can be expressed in terms of numbers, symbols, text, images or voice, etc., representing quantities, actions and objects. But it is complicated to describe knowledge and discriminate it from information. Data becomes “information” when it is placed into some context. Information reduces ambiguity and changes one’s way of thinking. Knowledge has become the most important asset or resource in contrast to information or data as it is not easily identified, understood, classified, organized, shared, measured or to imitate. Pantzar (2000) highlights that Data and information are components of the knowledge transmitted within the information society, in such a manner that data forms the level of the elements. Data is raw, simply exists and has no implication beyond its existence. It can subsist in any form, usable or not. It does not have meaning of itself. The transformation of data into information is thus a process of reception, recognition and conversion. Information and knowledge are probably the very concepts that have been confused most in the information society debate. Knowledge is to be understood as a phenomenon that is larger than information but uses information as its building material. If knowledge is “knowing how” to do something, wisdom is “knowing why, what and how” to do something. Wisdom also extends to the application of knowledge in action. A simplistic representation of the relationship between wisdom and knowledge is captured in the following expression:

Figure 2. Data to knowledge

Wisdom = Knowledge + Ethics + Action.

Helina and Harmaakorpi, (2008) are of the opinion that:

Data is the representation of an object. Information is the aggregation of data into something that has meaning (semantics) through interpretation by human or automated processes and Knowledge is that which is derived and inferred from assimilating information against perceived context, experience or business rules.

The schema depicted in Figure 2 reflects data, information and knowledge as distinct kinds of economic goods, each possessing a specific type of utility. The utility of data resides in the fact that it can carry information about the physical world; that of information, in the fact that it can modify an expectation or a state of knowledge; finally, that of knowledge in the fact that it allows an agent to act in adaptive ways in and upon the physical world. Telephone books are paradigmatically data goods; specialized newsletters, being more selective, exemplify information goods; and brain surgery can be thought of as knowledge good (Boisot & Canals, 2003).

Understanding the concept of data, information and knowledge is becoming increasingly important in relation to the design and development of electronic information. Information is a critical resource in the operation and management of organizations. Timely availability of relevant information is vital for effective performance of managerial functions such as planning, organizing, leading, and control. As and when the citizens of any nation become aware with the concept of information or in other words become information literate, it ensures the paramount research and development of the realm.

Features of Information

The features of good information are relevance, timeliness, accuracy, cost-effectiveness, reliability, usability, exhaustiveness, and aggregation level. Information is relevant if it leads to improved decision making. It might also be relevant if it reaffirms a previous decision. If it does not have anything to do with one's problem, it is irrelevant. Timeliness refers to the currency of the information presented to the users. Currency of data or information is the time gap between the occurrence of an event in the field until its presentation to

the user (decision maker). When this amount of time is very short, we describe the information system as a *real-time* system. Accuracy is measured by comparing the data to *actual* events. The importance of accurate data varies with the type of decisions that need to be made (Babu, Singh, & Sachdeva, 2013).

Value of Information

Information has a great impact on decision making, and hence its *value* is closely tied to the decisions that result from its use. Information does not have an absolute universal value. Its value is related to those who use it, when it is used, and in what situation it is used. In this sense, information is similar to other commodities. Information supports decisions, decisions trigger actions, and actions affect the achievements or performance of the organization (Babu, Singh, & Sachdeva, 2013).

Importance of Information

Good information is essential for effective operation and decision making at all levels in academics as well as business. Every society is surely an information society and every organization is an information organization. Therefore, information is a basic resource like materials, money and personnel. Information can be considered either as an abstract concept (ideas) or as a commodity, usually in the form of letters and reports. Essentially, therefore, information has become a critical resource, just like energy, both of which are vital to the wellbeing of individuals and organizations in the modern world (Adeoti-Adekeye, 1997). Kaye (1995) mentions that most managers would agree that good information is essential to the success of an organization. If an organization is to survive and prosper, it must understand both its own internal workings and the nature of the environment to which it has to adapt and respond. Good information improves decision making, increases efficiency and provides a competitive edge to the organization which knows more than the opposition.

Information Needs and Its Types

Information environment is enough rich, characterized by an increase in information sources as well as information providers, a variety of approaches and methods for accessing information, and a redundancy of content from multiple sources. In this “overloaded” information environment, many information users tend to experience a sense of insufficiency in locating the precise information which leads to anxiety. In this complex information environment, understanding the way individuals choose to satisfy their information needs takes on new urgency. Insight into information seeking can be gained by understanding how users seek information sources and how they locate the desired information to meet their needs (Chandra, Lynn, Lawrence & Lillie, 2007). The concept of information needs was coined by an American information scientist Robert S. Taylor in his article “The Process of Asking Questions” published in American Documentation (Now is Journal of the American Society of Information Science and Technology (Agropedia, 2015). There are many definitions of an information need. According to Krippendorf (1990) information need is a recognition that your knowledge is inadequate to satisfy a goal that you have. He explains that “having information” is not the same as “being informed.” Therefore, the problem is not in obtaining information but, rather in understanding the information that you do have. Each individual’s need is formed by the actual situation and by the way the individual defines that situation (Snunith & Sarah, 2007). Campbell, (2000) defines an information need as “the perception of a lack of information that provokes one to then develop a need for it.” Some information researchers incorporated the study of information need into the larger concept of information behavior which also includes information giving, seeking and use (Pettigrew, Fidel & Bruce, 2001), while others took the information need and believe it to be representative of the whole information-seeking process (Westbrook, 1993). Users’ information needs have indeed changed (and are still chang-

ing) as a result of the emergence and expansion of the electronic form in which information content is being made available for users' access and use (Kebede, 2002).

Numerous studies have been carried out which divulge that information needs change according to the nature of subject field and requirement of users. Some of which are:

Political Respondents need information mostly while preparing for debates, speeches and questions (Alemna & Skouby, 2000). Information needs of people with Medical professionals are seen to be complex as the needs change over time; variations in the desire for information; and there are differences in how information is needed due to the physical and psychological state of different patients (Mark, Janet & Nicole 2003). It is also found from the literature that Students in universities may need information in the following types:

- Educational information need,
- Health information needs,
- Employment information needs,
- Social needs,
- Political information needs (Silvio, 2006)

The information needs of teachers were found to be mostly related to guidance on administrative procedures, having lesson plans ready, mechanisms for evidencing work, etc (Williams, 2005). Further, information needs of the General people are found to be varied. The areas in which they needed information are diverse. These range from the information needs of the farmers, to that of the petty traders, artisans, blacksmiths, weavers, painters, fishermen, postmasters, labors, adult learners etc. Their needs, however, crystallized into the following major areas:

- Agriculture information needs.
- Health information needs.
- Political information needs.
- Educational information needs.
- Economic information needs.
- Social information needs (Momodu, 2002).

Use of Information Sources to Fulfill Information Needs

For fulfilling the information needs, users access different sources of information Sources. Scien-

Figure 3. Generation of information needs among users

tists, engineers and technologists in general use encyclopedias, handbooks, textbooks, periodicals, abstracts, indexes, standards, patents, etc. for their research and development works. He showed that information needs of scientists, engineers and technologists are equally based on their knowledge about those sources of information and accessibility of these information sources (Gayatri, 2006). Post Graduate students and Research Scholars mostly use journals, library books and textbooks for completing their course work (Fidzani, 1998). Wilson, (2006) shows through a model (Figure 3), the mechanism that helps to know how the information needs generates among the users of an information system as:

Types of Information Needs

Information age has driven every user towards a way where he needs information in various types and formats. As a result, multiple information sources have been generated to satisfy the user information needs. These needs have been categorized according to the users and their requirements into several types in different fields of knowledge. Moreover, it has been a topic of numerous research papers and information professionals from time to time.

Broadly, there are three types of needs:

- **Expressed or Articulated Need:** The need that is expressed.
- **Unexpressed Needs:** The user is aware of the needs but does not like to express it.
- **Dormant Needs:** The user is unaware about his need. However, Information service provider brings to light their needs.

However, information needs have been categorized into different types by various authors globally. Some of which are as:

Shenton (2007) divulges that information needs (Figure 4) can be divided into five broad categories:

1. Needs that are known to the individual but not to the information professionals.
2. Needs that are known to both parties.
3. Needs that are known to the information professional but not the individual.
4. Needs that are misunderstood by the individual.
5. Needs that are not known to either the individual or the information professional.

Khoir, Du & Koronios (2014) while discussing about the information needs of general people conclude that their need categories include: housing, schooling, health, banking and finances, driver

Figure 4. Types of information need as represented in a Johari Window

	Misunderstood by the individual	Known to the individual	Not known to the individual
Known to the information professional	Di <i>Misguided needs</i>	B <i>Expressed needs</i>	C <i>Inferred needs</i>
Not known to the information professional	Dii <i>Misguided needs</i>	Ai <i>Unexpressed needs</i> Aii <i>Independently- met needs</i>	E <i>Dormant or delitescent needs</i>

licenses, government-related issues, legal issues and practical information. While as, Alemna and Skouby (2000) reveal with regard to the type of information often sought by the MPs, these were varied and interesting. A broad categorization and ranking of the information types relate to the needs of the society. However, when considered in terms of hierarchy, most of the MPs considered information on rural development, agriculture, and human rights more important than information on foreign affairs and military.

Wilson has divided the information needs of a person according to the circumstance of his related environment (Work environment, Socio-cultural environment, Politico-economic environment) into three main types (Figure 5):

1. Physiological needs.
2. Affective needs.
3. Cognitive needs.

Factors Influencing Information Needs and Seeking Behavior of Users and Their Types

Information need is one of the cognitive needs of humanity. Information need determines information-seeking behavior and these concepts harmonize one another. Information need and information-seeking behavior are affected by many factors. It is observed from the data that 'information scattered in too many sources' and that too in multi-formats is the problem often faced by users. The users sometimes face problems such as needed information is not available in library, incomplete information in sources, do not know how to use online catalogue, do not know how to use electronic resources, lack of information skills to search and internet speed is slow (Kadli & Kumber, 2011). Some early studies suggest that demographic factors such as tenure, experience,

and education affect information seeking behavior (Keller & Holland, 1978; O'Reilly, 1982). Some of the authors are of the opinion factors influencing information seeking behavior of users are of the following types:

1. **External Factors:** These are the factors that include social, organizational, time, navigation, project, demographics and other external factors.
2. **Internal Factors:** These include the factors related to the internal ability and skills of user like the previous knowledge, information literacy, level of experience, self-precision, self- efficiency etc.

Broadly speaking, most of the authors and researchers found that factors influencing the information seeking behavior of users are of two main categories (Figure 6 and Figure 7) viz:

- Micro
- Macro factors

Both the types are discussed as follows.

Micro Factors

The literature related to the factors responsible for influencing information seeking behavior of users reveal that demographics (gender, nationality and age), discipline, level of study, type of enrolment, stage of study, pedagogy etc are the micro factors of information-seeking behavior.

Demographic Characteristics

Some demographic characteristics that directly or indirectly influence the Information seeking behavior of users are as:

- **Gender:** Gender is believed to play an important role in the information seeking behavior of users. Some studies show female have higher social-cultural, and psychologi-

cal adaptation scores than male. However, others reveal that women have lower competency in using computerized library resources and technologies. As most database searching requires pervasive computer use and familiarity, it could affect their ability on Information seeking behavior There-fore, males were more satisfied and confident and had fewer difficulties than females. As revealed by Al-Muomen, Morris and Maynard (2011), gender issues were also considered problematic by some focus group attendees. Many universities in the Arab world, segregate students in the classrooms according to their gender. Male and female students were separated at Kuwait University in 1996. According to the responses of one of the attendees “segregating genders on the campus had led to a big deterioration in the level of education in the country”. Another noted that since genders are now separated in campus and says “sending a mixed group of males and females as a group to work in the library on a research project has obvious consequences”.

- **Nationality:** Studies reveal that level of adjustment of students from different nationalities have a good effect on Information seeking behavior. It could be because of the cultural, language and education system that may be highly influencing the information seeking of users.
- **Age:** Age of the users can affect the information seeking behavior of users. They learn skills and become more educated with age in an academic institution. Postgraduate students are usually older than undergraduate students, they may have advanced level of library skills information literacy and may be more aware with online recourses and search engine which have been used during undergraduate degree. Meanwhile, an old person may lose his remembrance which may prove adverse to his information seeking behavior.

- **Financial Problem/ Income:** If students are wealthier and financially well, they can have better electronic gadgets and get more services than those that are financially weak. Chen (2010) indicated that wealthier immigrants are more adaptive to the host country. It may be because they can visit host country more and had more opportunities to participate to more ceremonies of the host country which makes their social adjustment easier and hence influences their information seeking behavior.

Cultural Aspects

Cultural factors may be viewed as those aspects of culture that members of cultural groups have acquired, intentionally or unintentionally, and carry with them where ever they go. When cultural factors of one group or one individual interface with another culture, it is quite likely that some form of dissimilarity will occur. Such dissension offers the potential for misunderstanding and in the information seeking environment it frequently leads to less-than-successful learning experiences for those who are cultural outsiders and leads to frustration, loss of motivation, and decline in self-esteem and individual value. It is good to say that the role played by cultural factors is highly influencing the information seeking process of students (Chen, 2010).

Information Literacy

A person must be able to recognize when information is needed and have the ability to locate, evaluate, and use effectively the needed information. To produce such skilled learners' schools colleges and universities appreciate and integrate the concept of information literacy into their learning processes and that they play a leadership role in equipping individuals and institutions to take benefit of the opportunities inherent within the

information society. Information literate people are those who have learned how to learn. They know how to learn because they know how knowledge is organized, how to find information and how to use information in such a way that others can learn from them. They are people prepared for lifelong learning, because they can always find the information needed for any task or decision at hand (Susie, 2005). Hence, Information literacy greatly influences the information seeking behavior of users.

IT Skills

The more competent the students attain their IT skills, the more highly they are able to locate suitable resources and to use the online databases. They are also more aware of the e-resources and experience fewer problems while using computers and networks for online searching purposes than students who have less IT skills.

Psychological Factor

Psychology plays a pivotal role in influencing the information seeking behavior of students. Before the relevant information is retrieved the students must overcome possible barriers, which sometimes are psychological. They must experience the situation as gratifying enough and themselves as competent enough to actually take the final decision to seek information. Motivation and interest influence the way information is used and evaluated. More the student is interested in the topic, the more efficiently he seeks information about it. In the use of information systems just technical skills are not enough, positive attitude and self-confidence are needed in order to excel with the systems. Emotional aspects like feelings of dissatisfaction, annoyance, information overload, confrontation to new information and computer loathing may form barriers to the search process (As cited by Heinstrom, 2003).

Academic Influence

Teachers also influence the information seeking behavior of students by offering guidance on how to conduct a literature review, guide with their research process, and help them on how to use information resources. Teachers can also recommend journals and papers by renowned authors and can give projects and assignments that student require in their research. Available literature also reveal that academics do influence students information seeking behavior and play an important role in encouraging students to explore a wide range of information resources. The importance of academic influence on searching behavior has also been noted by other studies as revealed by Barrett (2005) and Tenopir (2003) (As cited by Al-Muomen, Morris & Maynard, 2011).

Macro Factors

The Macro Factors that influence the information needs of users are discussed as under:

Information Resource Design

Information resource design is a term given by Urquhart and Rowley (2007) to cover all the aspects relevant to the devise of training materials to facilitate students locate and use information resources successfully. In focus group discussions with graduate students, Urquhart and Rowley found that much training material provided by the library or staff members often lacked detail. In this study, students attending the focus groups also expressed concern about the lack of, and variability in, information resource training materials. For example, two students from Social Sciences pointed out that some academic staff used the same materials for both Bachelor and Masters' programmes without recognizing the need for it to be pitched at different levels.

Availability and Constraints to Access

Availability of good computer systems and internet access is one of the main influential factors related to information seeking behavior of students. Besides, slow internet access, electricity disruptions and database connection failures discourages the students in seeking precise information. Problems in obtaining usernames and passwords from a particular library to have access to its collection are other issue related to the students information seeking.

Policies and Funding

We are in an era when people cannot wait and every user needs information instantly. It calls for the Libraries to provide more services and facilities to its users and the libraries should not be just used as a quiet place of study. It is only possible when libraries possess enough financial resources to facilitate better services to its users. Lack of financial resources can become a major problem as this limited the purchase of books and access to databases. One academic solution suggested is that this could be partially overcome by having shared access to materials held in a consortium across universities

Organizational Knowledge and Culture

Organizational culture is another issue that surely will affect the information seeking behavior of students and users of its information sources. The time of working hours and the facilities like Photostat and printing as well as scanning, often needed by a student, can either enhance the skill of information seeking behavior of a student or can prove otherwise. Obviously, barriers and obstacles such as these will affect what, how and when information is sought.

Figure 6. Factors influencing the information needs of users

Information Learning Technology Infrastructure

Efficient virtual learning environment and use of webinars also have good influence on the information behavior of users. In their research in Kuwait

University, Urquhart and Rowley (2007) found that students praised the use of virtual learning environments for providing access to materials which enabled them to tailor their learning and to learn at their own speed. In this case, the majority of graduate students expressed concern over

Figure 7. Factors influencing the information needs of users

the lack of sufficient virtual learning materials and reported that the low usage of electronic information resources available through their library portals and virtual systems was, in part, a consequence of this.

FUTURE RESEARCH DIRECTIONS

Information needs of users have indeed changed (and are still changing) as a result of the emergence and extension of the electronic form in which information content is being made available for users' access and use. Information needs of users help in understanding and examining their Information Seeking Behavior and prove useful to select appropriate methodologies and adopt best techniques to carry out research in more systematic manner. These help in better understanding of tasks, activities, available services, infrastructure and problems faced by users while searching their needed information thereby help administrators and higher authorities to take right decisions, acquire relevant information sources, offer best services, implement tech savvy infrastructure and satisfy the information needs of users. This study has a vast scope for future research. It can be extended to study and highlight the information needs of Professors, Lecturers, Teachers, Post Graduate & Under Graduate Students associated with teaching and learning processes in different Colleges and Universities globally. Further, research can be extended towards exploring information retrieval and information seeking models.

CONCLUSION AND SUGGESTION

Information needs are highly related to the fields of study of users and shows a remarkable diversion in their nature. Further, knowing the information needs of various users in diverse fields of study will surely help to understand the information seeking behavior of users. There is great diversity

in the information needs of users depending upon the field of study with which they are associated. In general, these needs are Physiological needs, Affective needs and Cognitive needs. Information need determines the information-seeking behavior of a user and is affected by many factors. There are two main types of factors viz Macro and Micro Factors. Macro Factors include Information resource design, Availability and constraints to access, Policies and funding etc. while as Micro Factors include demographics (gender, nationality and age), discipline, level of study, type of enrolment etc.

KEY TERMS AND DEFINITIONS

Information: Information is an assemblage of data in a comprehensible form capable of communication and use.

Information Behavior: Information behavior refers to how people approach and handle information. **Information Literacy:** The ability to know when there is a need for information, to be able to identify, locate, evaluate, and effectively use that information for the issue or problem at hand.

Information Need: The perception of a lack of information that provokes one to develop a need for it.

Information Seeking Behavior: A special case of problem solving which, includes recognizing and interpreting the information problem, establishing a plan of search, conducting the search, evaluating the results, and if necessary, iterating through the process again.

Knowledge: When the information is interpreted or put into context, or when meaning is added to it, it is converted into knowledge.

A Maturity Model for Digital Literacies and Sustainable Development

INTRODUCTION

It is a given that the world is now becoming increasingly digitalised. However the speed at which this digitisation has occurred, has led to unequal progression amongst societies. A key aspect of digitisation is the notion of “digital inclusion”; the empowerment of individuals through digital participation. Successful initiatives, supported by digital literacy, have enabled those that are isolated to gain on a social and economic front (Sharma & Mokhtar, 2006). This paper recounts the role of digital literacies in supporting participative, and therefore sustainable, development. Taking a historical development perspective, the paper concludes with a maturity model that links digital policies with socio-economic well-being.

Building on the pioneering work of Gilster (1997), Belshaw (2012) offers a comprehensive definition of modern literacies in digital society:

Literacies involve the mastery of simple cognitive and practical skills. To be ‘literate’ is only meaningful within a social context and involves having access to the cultural, economic and political structures of a society. In addition to providing the means and skills to deal with written texts, literacies bring about a transformation in human

thinking capacities. This intellectual empowerment happens as a result of new cognitive tools (e.g. writing) or technical instruments (e.g. digital technologies). (p.90)

It has been suggested that digital inclusion and participation enables the grassroots to be engaged, bridging some of the prevailing socio-economic disadvantages (SEDs) that exist within societies, as well as across countries (Armenta et al., 2012). This is the fundamental premise of digital literacies – the set of skills and tools that will empower individuals and groups to participate fully in the increasingly digital future and hence bridge the disparities in socio-economic opportunities.

BACKGROUND

The Evolution of Digital Literacy

Lanham (1995) first conceptualised digital literacy as the ability to comprehend information, regardless of the medium. This definition focused on the user’s ability to navigate between the various online and offline mediums. Since this original conceptualisation, the term digital literacy has evolved along with pervasive Information and

Communication Technology (ICT) in society. While Lanham created awareness of the need to comprehend the transformations brought about by the incorporation of ICTs, it was Gilster (1997) who popularised the concept of digital literacy and its emergence as a critical skill. His portrayal of digital literacy as “mastering ideas, not keystrokes” (1997, p.15), positioned the concept to focus more on cognitive ability, as opposed to competencies. This was considered a milestone, as society rapidly digitised and network effects arising from social media led to the development of social capital as a socio-economic advantage.

Building on this, Eshet-Alkalai (2004) presented five survival skills for the digital era: photo-visual literacy, reproduction literacy, information literacy, branching literacy and social-emotional literacy. Of these five digital literacies, four of them are largely based on specific digital skills. As the contrasting element, socio-emotional literacy is of particular interest. The definition of socio-emotionally literate users offered by Eshet-Alkalai (2004) is individuals who are able to work with others, sharing and evaluating information and knowledge, in order to construct new knowledge. This refers to the participation and communication that occurs in the digital world, as well as the opportunities offered via this medium. Where participation leads to collective intelligence, new knowledge may be developed. By situating socio-emotional literacy as a digital literacy skill, the Internet and new media present a new cultural environment, with its own unique values and practices for engagement.

The socio-cultural dimension of digital literacy is further discussed by Bélisle (2006). Although her work focuses on a re-conceptualisation of literacy and not merely digital literacy, Bélisle’s research is important as it explains the changes to society as a result of the digital knowledge revolution. In fact, it could be said that Bélisle (2006) truly grasped the essence of the changes to the concept of literacy within the digital society. Bélisle (2006) examines three dimensions of literacy: Functional, Socio-cultural and Transformational. Functional

literacy refers to the basic skills required to lead a day-to-day life. In the conventional sense, this refers to the skills of reading, writing, speaking and listening. In relation to digital literacies, this includes the ability to perform operational computer skills, such as input, output and searching, but also the ability to understand when and where each skill set is relevant. This dimension of digital literacy could be read in parallel with Lanham’s original concept.

Bélisle’s second dimension of literacies is the socio-cultural. Literacy ultimately serves to address a purpose; it “[gives] access to, and understanding of, the structures of power and authority through mastery of written texts and numbers” (Bélisle, 2006, p.53). Socio-cultural literacy includes knowledge of a society’s values, attitudes, practices and conventions; and an understanding of where each of these apply. This is important in relation to digital literacy, as the digital world provides new channels for participation and communication. Literacy is only meaningful when contextualised to the cultural fabric of society; the socio-cultural dimension of digital literacy enables individuals to immerse themselves within and to participate in social and economic structures of digital society. Hence, when referring specifically to digital literacy, it may be more accurate to consider the socio-cultural dimension of literacy as a “socio-economic” function. This would better capture its *impact on* and *empowerment of* users in online communities.

The final dimension of literacy which Bélisle describes is the transformational dimension of digital literacy. This “brings a profound enrichment and eventually entails a transformation of human thinking capacities” (Bélisle, 2006, p.54). The individuals’ intellectual empowerment through literacy may have the power to transform society, especially where creative cognitive ability leads to the creation of new cognitive tools (Bélisle, 2006). If Bélisle’s transformative digital literacy is viewed alongside Eshet-Alkalai’s socio-emotional literacy, the online world opens up new opportunities for collaboration and creation. This ultimately

brings new knowledge to society, transforming it and those within it.

More recently, Belshaw (2012) has utilised the term digital literacies, rather than digital literacy, both to avoid reducing it to a finite outcome, as well as to address the complexity of the concept. Belshaw (2012) presents eight, non-hierarchic elements of digital literacies: Cultural, Cognitive, Constructive, Communicative, Confident, Creative, Critical and Civic. Within these elements, it can be seen that digital literacies have evolved from a mere set of skills, to encompass cognitive ability, to facilitate cultural engagement, and to enable critical analysis. Continuing the evolutionary path of digital literacies, Belshaw's research (2012) can be seen as particularly prominent, especially where it links the element of "Cultural" to that of "Civic". This emphasizes participation, social justice and civic responsibility; digital literacies are not simply about functional ability but also about the inclusion, participation and empowerment that result from socio-cultural interaction. Belshaw's work draws heavily on Bélisle's; his definition of literacies feeds directly into Bélisle's proposed three

dimensions of digital literacy. Linking Belshaw's work to Bélisle (2006), transformative digital literacy can go beyond the ability to transform an individual through self-enhancement to transforming societies through these "entitlements" gained by individuals.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

Levels of Digital Development

The development of a digital society takes place in levels, each of which lays the foundations for the succeeding ones. In the context of the digital divide, Armenta, Serranob, Cabrera and Conte (2012) propose four levels to development; each centred on a key tension point (see Figure 1).

The first level addresses the problem of access, distinguishing between those who have access to the infrastructure and those who do not. The second level focuses on usage, in terms of the social-economic indicators governing usage, while

Figure 1. Levels of digital development

the third level addresses the role of participation within the digital divide and focuses on the need for human development through participation.

Armenta et al. (2012) further suggest that we are currently entering the fourth level of digital development, where digital inclusion must be mediated by human values. At this level, there comes a focus on the need for community involvement and technology adoption. Harding (2016) argues that while the digital world had promised to create a level playing field by creating equal access to information, such information possesses a different cost to different individuals in accordance to their socio-economic status. This highlights the importance of digital inclusion to enable a level playing field. While each level of the developmental model seeks to discourage digital exclusion, it is the fourth level of human values which has the potential to ensure that as society progresses, the socio-economically disadvantaged (SEDs) do not get marginalised and dis-enfranchised. Thus, the links between the civic and cultural elements in Belshaw's model draws parallels to the fourth level of "human values" in work by Armenta et al. (2012) on digital inclusion.

Further analysis of Armenta et al.'s model (2012) has shown each level to reflect different dimensions of digital literacies. This can be seen through adopting a modified lens of Bélisle's (2006) digital literacies and applying it to Armenta et al.'s model (see Figure 2).

A juxtaposition of Bélisle's work (2006) examines three dimensions of functional, socio-cultural and transformational literacies. This provides further clarification of the four developmental levels in Figure 1, by linking digital literacy with digital development. Access (level 1 of development) may be mapped directly to the outcome of functional literacy as without the former, one cannot possibly achieve the latter. Usage and participation (levels 2 and 3) normally lead to socio-cultural (or interchangeably socio-economic) participation. The subtle difference between usage and participation is that while usage is transactional, participation also involves the production of social (emotional) capital. Finally, at the highest level of human values, individuals and society transforms into knowledge societies (again, from the foundations of information societies enabled in levels 1 and 2).

Figure 2. Model of digital development as supposed by digital literacies

As the fundamental argument, bridging digital disparities to access and usage of technologies must be supported by individuals' functional abilities to utilise these tools. Going further into the model, it can be seen that usage still draws upon the socio-economic function of digital literacies. Armenta et al. (2012) discusses how at the second level, applications suited to the needs of the population were incorporated to bridge an existing digital usage divide. There are ample opportunities to develop context relevant applications, opening up new ways of gaining socio-economic status. It may also be said that usage of these applications draw on the socio-economic dimension of digital literacies, as one is able to participate meaningfully within society.

Mansell and Tremblay (2013) have suggested that human development is the process of improving and increasing each individual's choices. The socio-economic dimension of digital literacies can indeed enable this by opening up opportunities for grass-root participation and community leadership through creating meaning around these activities. This increases inclusion in society, and may enable improvement of one's economic status. Morris and Morris (2013), for example, have revealed that Internet access and usage could reduce the socio-economic gap in knowledge and participation. Beyond the socio-economic dimension, level three of participation also supports the transformative capacity of digital literacies. The digital environment holds a myriad of potential for users who are empowered to explore them; digital literacies can open up opportunities for individuals to transform themselves, their abilities and their circumstances.

This final level of human values is demonstrative of transformational digital literacy beyond self-enhancement to enable societal development. As discussed by Belshaw (2012), the digital environment creates new civic responsibilities for users. Relating back to Armenta et al.'s model, the fourth level of human values must comprise an element of civic responsibility to enable society's transformation through community involvement

and technology adoption. By drawing on human values, this level will promote digital inclusion for all.

Digital Maturity and Sustainable Development

"Knowledge societies will not really be worthy of the name unless the greatest possible number of individuals can become knowledge producers rather than mere consumers of already available knowledge." (UNESCO, 2005, p.189). Indeed, UNESCO's further probing (Mansell & Tremblay, 2013) highlights the need for knowledge societies to be based on inclusion to ensure their sustainability. The 2013 report underscores the importance of human values for digital inclusion and participation. The need to respect, welcome and appreciate new ideas is key to building an innovative and sustainable society.

Prior work by Sharma and his associates highlight key characteristics of knowledge societies: 1) they are necessary and sufficient conditions for growth in the knowledge economy, 2) they have high knowledge absorptive capacity and complex chains of creation, production and distribution, and 3) they consist of a sustainable learning community which emphasises innovation (Sharma, Ng, Dharmawirya & Lee, 2008). Four knowledge pillars actively used by the World Bank's Knowledge Assessment Methodology (information infrastructure, economic and institutional governance, education and human capital, and innovation system) have been effective in deriving a set of best practices in developing knowledge policies (cf Sharma et al., 2008; 2009; Chandrasekar & Sharma, 2010). However, these studies did not examine participation gaps arising from the uneven distribution of resources in developing skills and literacies throughout the world, and the lack of transparency in the way digital literacies shape perceptions of the world. At this juncture of the new participatory culture, the key question of "how we can guarantee that the rich opportunities afforded by the expanding

digital landscape are made available to all,” still remains unanswered.

Knowledge societies which are based on an institutional framework that supports collective security system and wider welfare can lead to sustainable development (Spangenberg, 2005a; 2005b). As a knowledge society is based on the need for knowledge distribution, access to information and skills to transform information into knowledge, inclusion within such societies is imperative. This may bridge the existing disparities within society and subsequently, promote sustainable development, where progress benefits all and no one gets left behind.

Synthesising the discussion in the previous section with the gap in prior work identified, the relationship between knowledge societies, digital inclusion and digital literacies may be examined through a proposed *Digital Literacies Maturity*

Model (DLMM) (see Figure 3 below). A maturity model is an assessment tool used to evaluate an entity (e.g., an organization) or a process. The term “maturity” relates to the degree of optimization of practices. Typically, a maturity model formally defines steps and result metrics which are applied to the management of best practices and active optimization of processes (Humphrey, 1988). Our proposed DLMM combines the World Bank’s four knowledge policy pillars with the four levels of digital development and provides a framework on how to promote sustainable development and socio-economic well-being.

Please note that the colouring of the cells in Figure 3 correspond to the different levels of literacy identified in Figure 2 above. Each cell in the matrix has a focus theme that characterises knowledge policy for a given pillar and level of development. For example, at the most basic level of

Figure 3. Digital literacies maturity model

	GOVERNANCE	INFRASTRUCTURE	EDUCATION & HUMAN CAPITAL	INNOVATION
HUMAN VALUES	<i>Sustainable Growth & Development</i>	<i>Community Involvement & Socio-economic Returns</i>	<i>Civic Responsibility</i>	<i>Collective Intelligence</i>

USAGE	<i>Training</i>	<i>Applications</i>	<i>Skills & Experience</i>	<i>Information Economy</i>
ACCESS	<i>Universal Service Obligation</i>	<i>Devices & Networks</i>	<i>Utility</i>	<i>Efficiency & Effectiveness</i>
DL Maturity Model Key	Functional Digital Literacy	Socio-economic Digital Literacy	Transformational Digital Literacy	

digital development (the access level), governance policies mainly focus on universal service obligations extracted by the regulator from licensed service providers so that no segment of society is excluded from access to basic digital services such as telephony, Internet, cable television and so on. The infrastructure dimension focuses on improving access to devices and networks and the training is geared towards utilitarian functions. Most innovative efforts are engaged in improving access, efficiency and effectiveness. Assuming prevalence of internet access is achieved, the next level focuses on the usage. Government policies promoting skill-based training and applications are essential to the development of an information economy. When both internet usage and access becomes common place, the next question to be asked is how to accelerate digital participation, such as grassroots participation, community leadership and knowledge exchange. Likewise at the highest level of digital development (the human values level), innovation policies must seek to capture the collective intelligence of the masses (sometimes known as the wisdom of the crowds).

However, the field success of the DLMM is dependent on the research methodology chosen. In empirical research conducted on digital literacies (Bonfadelli, 2002; Hargittai & Hinnant, 2008), quantitative data analysis appears to be the preferred research methodology. However, when examining, for example, Hargittai's (2009) web-oriented survey measures to gauge digital literacies, the research may be adequate in capturing functional digital literacy, but its methodology completely overlooks the socio-economic and transformation dimensions of literacies, which is a cause of concern. As ICT becomes increasingly user-centric, functional ability becomes less of an issue as compared to the ability to utilise technology in meaningful ways. In contrast, Canada has provided a vision for 21st century citizens to possess and maintain values that enable them to effectively communicate "to flourish in groups of individuals with multiple-perspectives who care deeply about a topic and are empathetically

responsive to each other's perspectives" (Hoechsmann & DeWaard, 2015, p.19).

The use of DLMM allows an economy to have its digital literacies and sustainable development processes assessed according to a conceptual framework with a clear set of benchmarks. Maturity is indicated by achieving a particular "Maturity Level", which provides a consistent set of measurements for researchers. For policy makers, the DLMM allows a knowledge society to compare its maturity level with other economies, or other parts of their own economy and derive specific recommendations for improvements. As such, a recommended approach to the field usage of the DLMM would be to create narratives, which allows space for quantitative hypotheses as well as data collection (Sharma et al. 2012). The creation of narratives and the application of the DLMM to these narratives could yield more in-depth and interesting results as compared to other methodologies. The details included through the choice of narrative approach thus become more applicable in relation to the levels of maturity (access, usage, participation, values) than the policies. For knowledge societies, it would be argued with choice narratives that government policies have been situated at the fourth level of human values in the digital development model. Whether this has led to sustainable development can be tested by tracking specific policy indicators of governance, infrastructure, education, and innovation.

SOLUTIONS AND RECOMMENDATIONS

Implications of DLMM for Digital Policies

Policies which encourage the continued evolution of knowledge societies must be constructed on the twin principles of inclusion and be supported by digital literacies to best enable the formation of sustainable knowledge societies. As the flowchart below illustrates (see Figure 4), governance can

Figure 4. Flowchart mapping the relationship between knowledge society pillars, digital development levels, and digital literacies

bridge the access divide through their universal service obligations, ensuring that the Internet is made equally accessible to all citizens as a digital entitlement. Infrastructure, built with the intention of bridging the access divide, can create accessible devices and networks for all. Utility may be enabled where access is supported by education and human capital. Innovation systems which enable access can create an efficient and effective society. However, these access policies must still be supported by functional digital literacy for users. Access is redundant when functional ability is absent.

Socio-economic literacy builds on functional literacy, to create meaning behind activity. On the second level, digital inclusion can be enabled through promoting usage. Government policies can enable usage through training, however these activities only have meaning when viewed through the lens of socio-economic literacy. Infrastructure may create applications tailored to the needs of the population, however it is with socio-economic digital literacy that users are motivated to utilise them. Skills obtained through formal education and life-long learning must be similarly motivated by the socio-economic dimension of literacy which creates meaning around the activity; the functional ability to use software and applications is only meaningful when understanding its socio-economic uses, purposes and relevance to the workforce. Human Capital provides the opportunity to gain experience with using technology. It is

important for individuals to use these experiences appropriately in a given context. For example, an individual can progress from being a passive receiver of technology to an active information consumer with effective searching skills. At the highest level, he or she can apply computational thinking skills and use the information intelligently to create value. This, again, results from digital literacies' socio-economic dimension. Finally, when innovation is supported by usage, it will facilitate the creation of the information economy, as the first step toward knowledge societies.

Through empowering people with socio-economic and transformational literacies, this may open up opportunities for digital citizens to improve their socio-economic status. The third level of digital inclusion focuses on the participation divide. Governments seeking to close the digital divide by bridging the participation gap may implement policies to promote grassroots participation supported by socio-economic digital literacy to create meaningful supporting participation. Infrastructure with the goal of achieving participation can incentivise human development, especially if it is supported by socio-economic literacy. Education and human capital, when directed toward bridging the participation divide, can enable community participation and create community leadership, as supported by socio-economic literacy. Finally, the key to the development of knowledge societies is innovation-supported participation. This can cre-

ate exchange of knowledge, which is catalyzed by transformational literacy.

Transformational literacies are especially key to the fourth level of human values. With transformation literacy as a goal, governance supporting human values can enable sustainable growth and development. Infrastructure with human values can allow community involvement and subsequently, social capital returns. Education and human capital supported by human values will create a sense of civic responsibility toward society; and innovation supported by human value will lead to the expression of collective intelligence.

FUTURE RESEARCH DIRECTIONS

When viewing the digital maturity model alongside Bélisle's conceptualisation of literacies (2006), it is apparent that digital literacies are necessary to support participation and subsequently, inclusion. The need to promote digital inclusion, especially through imparting digital literacies, becomes increasingly important for policy makers

in light of the value placed on knowledge within the modern economy and the drive for countries to construct sustainable growth and development.

Frameworks and measures conceptualised by government and policy makers have been developed with the intention of bridging the digital divide. The European Union and Canada, for instance, have developed conceptual frameworks of digital literacies and measures, with a focus on education and creating the 21st century citizen. When developing frameworks through which to build knowledge societies, it is important that governments and policy makers keep in mind that inclusion must serve as the foundation to such societies, not merely an afterthought. The Digital Literacies Maturity Model presented in this article is intended as a map to the creation of sustainable knowledge societies.

In this regard, the Maturity Model may be re-presented as a table of questions for policy makers. This will enable them to determine whether policies under development place adequate emphasis on digital inclusion (see Figure 5).

Figure 5. DLMM for policy making

	GOVERNANCE	INFRASTRUCTURE	EDUCATION & HUMAN CAPITAL	INNOVATION
HUMAN VALUES	<i>How can governance promote human values?</i>	<i>How can infrastructure promote human values?</i>	<i>How can education and human capital promote human values?</i>	<i>How can innovation promote human values?</i>
PARTICIPATION	<i>How can governance promote participation?</i>	<i>How can infrastructure promote participation?</i>	<i>How can education and human capital promote usage?</i>	<i>How can innovation promote participation?</i>
USAGE	<i>How can governance promote usage?</i>	<i>How can infrastructure promote usage?</i>	<i>How can education and human capital promote usage?</i>	<i>How can innovation promote usage?</i>
ACCESS	<i>How can governance promote access?</i>	<i>How can infrastructure promote access?</i>	<i>How can education and human capital promote access?</i>	<i>How can innovation promote access?</i>

By examining policy-making decisions in this manner, digital development may thus be promoted. In addition, at every level, these decisions must be supported by the knowledge of what kinds of digital literacies are necessary to fulfil the requirements of that level. This will enable the formation of knowledge societies on the basis of inclusion.

CONCLUSION

This article has provided a link between digital development and digital literacies. It highlights that in order to reach the level of human values, there needs to be a shift from functional literacy to transformational literacy. This means that the current and future generations need to be supported with other competencies to enable them to be part of sustainable knowledge societies.

Digital literacy can promote inclusion, and reduce socio-economic disparities by promoting participation at an economic level. In order to enable widespread inclusion, knowledge societies need to develop in line with digital inclusion policies. The maturity model presented in this paper brings together these two concepts, offering policy makers the opportunity to identify key areas of development, and ensuring a digitally enabled future.

KEY TERMS AND DEFINITIONS

Digital Development: The various levels of the digital divide which must be bridged to promote wide spread digital usage within a society.

Digital Literacy Maturity Model: A consistent set of measurements for researchers to study digital literacy in accordance to the level of digital development within knowledge societies.

Digital Literacy: Digital literacy consists of competence in the basic skills to utilize digital technologies, an understanding of how these competences may be utilised to create context to practices and subsequently to participate socially, culturally and economically, and it allows for the intellectual empowerment of individuals to transform society.

Functional Digital Literacy: The basic competences or skills necessary to engage in the digital society.

Knowledge Societies: Societies which possess the necessary and sufficient conditions for growth in the knowledge economy, have high knowledge absorptive capacity and complex chains of creation, production and distribution, and consist of sustainable learning communities which emphasise innovation.

Socio-Economic Digital Literacy: the ability of digital users to engage in the social and economic structures of the digital society.

Sustainable Development: The process of developing while ensuring that the development does not promote existing inequalities, nor does it hinder the resources and abilities for future generations to continue to develop and progress.

Transformational Digital Literacy: The empowerment of digital users, to be transformed intellectually, which ultimately changes society.

Aman Yadav

Michigan State University, USA

INTRODUCTION

Multimedia platforms such as blogs, social networks, forums, and video sharing websites have become a key component of communication in the 21st century. Ranging from flash news, popular press, and activism to trends, scandals, and advertising, these platforms have also become a repository of media and information in today's hyper-connected society. Both individuals and media professionals often create, curate, and circulate content (i.e., user-generated content) in digital media spaces, thereby saturating media spaces with images and information that shape our digital culture (Gleason, 2013). Possessing the competencies to understand how information is conveyed through digital media is therefore an important skill to empower citizens to recognize its functions and effects on human communication. To address these objectives, the United Nations Educational, Scientific, and Cultural Organization (UNESCO) developed a media & information literacy (MIL) framework that encompasses the skills needed by 21st century citizens to critically evaluate information communicated through different media sources (UNESCO, 2013). Drawing from the UNESCO MIL framework, this chapter examines the skills needed by individuals to evaluate information presented through digital mass media, and discusses the role that educators can play in its instruction. The next section provides a brief history of MIL, followed by a look at the specific competencies that compose MIL.

Then, the chapter proceeds to discussing the role of educators in MIL instruction and concludes with the implications of MIL implementation in educational settings.

BACKGROUND

What does it mean to be literate in the 21st century? While literacy has traditionally been contained to reading and writing skills, communication in the 21st century has expanded these customary views of literacy into an ever-evolving concept (Hobbs & Jensen, 2009). In today's world, unfiltered information is available across multiple media platforms, such as television or newspapers, but more particularly on the Internet. Because media and other information providers are instrumental in shaping the perceptions, beliefs, and attitudes of individuals in today's digital age (Guzzetti & Lesley, 2015), being literate in today's society therefore includes being able to read, write, and communicate across a range of platforms, tools, and media. As a result, individuals need to master an array of literacy skills beyond basic reading and writing abilities (Livingstone et al., 2014). Citizens who are not aware of how media and information systems function are more likely to accept media messages as facts, while individuals who possess media and information literacy skills are able to evaluate and draw their own conclusion from the constant flow of mediated information (Potter, 2004).

Media & Information Literacy (MIL) is an umbrella term that bridges information literacy with media literacy. Because the Internet is a digital platform that hosts multitudes of archives of mediatized information, navigating 21st century digital information implies the convergence of different sets of skills to address the challenges of our globalized world. Modern information systems are complex and multifaceted, and require individuals to be informed and engaged citizens in order to make sense of the mediatized information that surrounds them. MIL thus describes the 21st century skills that individuals need to critically evaluate information via various media sources and to become critical consumers of information (UNESCO, 2013). UNESCO (2013) articulated that media and information literate citizens should understand the importance of accessibility to information, know how to evaluate its veracity, and use it in ethical ways. Additionally, they should understand media functions and purposes, and engage with them for self-expression. For instance, individuals should be able to distinguish when media and information are used either for entertainment, decision making, problem solving, learning, or communicating with others. They should also understand how these purposes are related to the roles and the functions that different media play, and that based on these functions, different media adhere to different professional and ethical standards. With this understanding comes the ability to practice one's own digital skills to engage with media and information for personal purposes, such as creating user-generated content, evaluating the credibility of a source, or communicating with others. This conceptual view of MIL is represented in figure 1. below.

The social implication of being media information literate in the 21st century is informed participation in digital communication (Jenkins, 2009; Lee, 2013; UNESCO, 2013). MIL skills allow users to move from being passive consumers of digital information and media to being actively engaged in the information systems that shape their culture (Lankshear & Knobel, 2008).

For example, an informed media and information literate person would recognize and react to media biases when present, would engage in an ethical manner with online social exchanges, or would participate in a digital culture by creating content relevant to that culture. MIL skills not only foster individuals' critical thinking and engagement with contemporary issues, but also allow them to take part in our era's "participatory culture" (Jenkins, 2009). A participatory culture allows users to communicate through the creation of content to actively use media to engage audiences (Jenkins, 2009). Therefore, participants who are equipped with MIL skills can help shape today's digital society and draw their own conclusions from the media and information that structures their culture, instead of simply accepting these media messages as unchangeable facts. Hence, possessing MIL skills can further the gap between those who participate in the culture, and those who do not because they have not acquired the necessary analytical and technical skills to do so (Jenkins, 2009).

UNESCO has focused on issues of media literacy since the 1960's, but acknowledged in the early 2000's that technology was changing the role of media in society and that soon, individuals would need to possess new skills to make sense of new types of communication and ways to access information (Frau-Meigs, 2007). In knowledge societies, information includes and depends on the process of communication, and as a result, media literacy and information literacy are intrinsically connected (Lau, 2013). Livingstone et al. (2008) argued that despite their traditionally divergent disciplinary backgrounds, the object of inquiry in both media literacy and information literacy started to be united to understand "the public's understanding of and effective engagement with media, information and communication technologies of all kinds" (p. 2). Koltay (2011) declared that one of the most salient commonalities between media literacy and information literacy was the analytical and critical thinking skills needed to interact with media and information.

Figure 1. A conceptual model of media and information literacy

Source: Grizzle et al. (2013)

UNESCO (2013) conjoined both media literacy and information literacy using the overlap of critical and analytical thinking practices in a new media & information literacy (MIL) framework. UNESCO recognized that for some, information literacy would be considered the broader area of study with media literacy as part of it, while for others media literacy would be seen as the broader field with information literacy as part of

it. UNESCO's MIL framework, therefore, sought to bridge these two terms together in light of the converging platforms that constitute 21st century communication systems, such as Internet-based media and information platforms, and proposed MIL as the umbrella term encompassing all other literacies, such as visual literacy and digital literacy. MIL is a broad transliteracy concept because it is meant to adapt to the ever-evolving

technologies and communication needs of a specific time or place. It can be applied to traditional media (e.g., books, print newspapers, television) as well as to contemporary media (e.g., Internet, online media), and offers the flexibility to be used in future information systems, regardless of their technology base or scope. Overall, MIL represents a set of analytical competencies that can transfer from one communication system to another and reflect the technological needs of 21st century digital communications. Given the scope of this encyclopedia, this chapter focuses specifically on digital communication and technology in the 21st century while acknowledging that MIL can be applied to and practiced in more traditional communication systems as well.

MEDIA AND INFORMATION LITERACY

A 21st Century Competency

Thanks to web-based technologies and digital media in the 21st century, individuals have more and more opportunities to become creators of knowledge and to take part in societal issues rather than simply being passive consumers of information (Buckingham, 2015; Lankshear & Knobel, 2008). UNESCO's media & information literacy framework provides a set of competencies, or in other words a set of knowledge, skills, and attitudes, that aim to empower citizens to critically evaluate and understand the contents of today's media and information systems (UNESCO, 2013). Because MIL relies on a combination of technical, analytical, and creative skills, it is a literacy that transcends media and type of information. That is, one can apply MIL skills while reading a novel or a newspaper, while watching television shows and advertisements, while surfing the Internet, or while engaging with others on social media. Because of the multi-faceted aspect of online communications in the 21st century and the increasing reliance on the multimodal transmission

of information (e.g., visual, textual, audio, etc.), this chapter emphasizes MIL competencies in the context of digital communication.

It is important to note that in the context of 21st century communication, the term media corresponds to the means by which information is delivered, and can be both professionally produced content—typically labeled as “the media”—or user-generated content. Furthermore, UNESCO (2013) described information literacy as the skills required to seek, evaluate and create information for personal, social, educational, or professional needs (Wilson et al., 2013). Together, being literate in terms of media and information, therefore, involves the ability to recognize the power of media, to evaluate the content of the information they convey, and to produce user-generated content (Moeller et al., 2011; Wilson et al., 2013). UNESCO (2013) summarized these MIL components under three main competencies: access and retrieval, understanding and evaluation, and creation and sharing (UNESCO, 2013). These competencies, along with their sub-skills, are represented in figure 2.

While analytical skills are central to MIL to evaluate media content, developing the retrieval and the creative aspect of MIL skills also relies on a set of technical skills that are intrinsically linked to technology and information systems in the 21st century (Davies, 2011; Jenkins, 2009; Wilson et al., 2013). Understanding how to access and retrieve information, along with knowing how to create and share personal content online depends on the mastery of technological and computing abilities. These skills are reviewed in the following section.

Media and Information Literacy in a Technology-Driven World

In today's digitally connected world, technology is pervasive from the use of social media (e.g., Facebook, Youtube, Snapchat, etc.) to the widespread presence of mobile devices (e.g., smartphones, laptops, tablets, etc.). A recent survey found that 95% of teenagers go online on

Figure 2. MIL components

Source: UNESCO, 2013

a daily basis, 72% of all teens spend time with friends via social media, and 79% of all teens use instant messages with their friends (Lenhart, et. al, 2015). These staggering numbers highlight the need for young individuals to understand issues related to privacy and security on the Internet, as the risks they encounter in relation to anonymity, persuasion, or cyber-bullying grow exponentially (Livingstone & Brake, 2010).

The key to developing individuals' competencies in MIL involves creating awareness of how computerized communication and web-based digital media work. As young citizens become better informed about how information travels over the Internet, they will better understand its implications for privacy and security of information in digital communications. One of the prerequisites for MIL in a digital world is to form a solid foundation of technological skills—often referred to as ICT (Information & Communication Technology) skills (Wilson et al., 2013). For that reason, MIL also has a natural connection to components of computational thinking (CT), which has been sug-

gested to be a 21st century cognitive and creative thinking skill that combines problem solving with principles of computing (Wing, 2006; DeSchryver & Yadav, 2015). For instance, one computational thinking idea that can support the development of MIL involves using “computational tools to analyze and study data and working with large data sets to analyze, visualize, and draw conclusions from trends” (College Board, p. 1). One of the key components of MIL is individuals' ability to access and critically evaluate information, particularly how information can be manipulated to deliver specific messages. As people engage in computational thinking activities to analyze and visualize data, they also develop important MIL practices of how information can be visualized to convey specific messages. Specifically, as individuals create data visualizations or communicate their ideas using a variety of media, they learn to negotiate how to best represent information to their audience, which would be determined by the essence of the message they want to convey for a specific purpose. This process of evaluat-

ing and presenting information to convey the gist of an idea allows individuals to critically assess the authenticity of the information encountered through digital media.

Recently, many nations have come to recognize the need for their youth to acquire technological skills and to prepare them to successfully manage 21st century information. For instance, analyzing scientific claims online, locating relevant research, building arguments from a variety of resources, or producing appropriate media contents are examples of standards now expected from students in the United States (Governors Association Center for Best Practices, 2010; International Society for Technology in Education, 2015; Next Generation Science Standards, 2013). These standards aim to benefit students' development of academic skills as well as personal and social skills in a digital world. A number of national and international educational organizations have also acknowledged the convergence and importance of student competencies in MIL and the need for students for being responsible users of digital media and information (Governors Association Center for Best Practices, 2010; International Society for Technology in Education, 2015; Next Generation Science Standards, 2013; Partnership for 21st century, 2014).

As an example, the national computer science curriculum in the United Kingdom highlighted the imperative need for students to “understand a range of ways to use technology safely, respectfully, responsibly and securely, including protecting their online identity and privacy; recognize inappropriate content, contact and conduct, and know how to report concern” (Microsoft, 2014, p. 42). Similarly, within the United States of America, College Board has launched a new advanced placement course entitled Computer Science Principles (CSP) that focuses on six computational thinking practices and seven big ideas of computer science. The CSP framework is designed to allow students to understand how digital manipulation and storage of personal information has implications for privacy and security of that data (College Board,

2014). Specifically, the CSP framework focuses on advancing students' understanding of how the Internet functions and grasping how computing can impact people and societies. While not labeled as MIL skills, there is considerable overlap between media & information literacy practices outlined in the UNESCO framework and the components in both the UK computing curriculum and the US computer science principles frameworks.

However, while using technology effectively to access and assess information and to effectively use media for communication is now considered an essential 21st century skill for students, teaching these digital skills requires educators to exhibit the same competencies themselves (Wilson et al., 2014). For MIL to become a leading practice in the 21st century and for students to acquire these skills, there is an urgent need to prepare educators in MIL instruction. The following section addresses the qualities that educators should possess to successfully integrate MIL in their teaching.

Educators' Role in Media and Information Literacy Instruction

In today's technology-driven and media-saturated world, educators will play a critical role in addressing the disparities that are emerging between those who can—or cannot—find, analyze, and critically evaluate information and media content to participate in their digital environments (Wilson et al., 2013). UNESCO in particular, envisioned that “initial focus on teachers is a key strategy to achieving a multiplier effect: from information-literate teachers to their students and eventually to society at large” (Wilson et al., 2013, p. 17). Preparing teachers to teach MIL skills is an essential step in order to promote 21st century MIL competencies at a large scale. The UNESCO MIL curriculum framework for teachers describes the competencies that educators should possess and provides examples for educators on how to embed media and information literacy practices in their teaching (Wilson et al., 2013).

According to the UNESCO, teachers should understand the role of media and information in their daily lives; understand media content and its uses; know how to access information effectively and efficiently; critically evaluate information; be familiar with both new and traditional media formats; and be able to situate the sociocultural context of media content (Wilson et al., 2013). UNESCO also identified various dimensions, including policy, curriculum and assessment, pedagogy, and professional training that need to be put into practice for the MIL framework for teachers to be successful (Wilson et al., 2013). For example, educators need to examine educational policies and national standards to better understand what role MIL might play in their own educational context. They also need to learn how to apply MIL to their teaching and understand students' interactions with media and information in their daily lives. In addition, educators must understand how MIL can be integrated in their school curriculum and how they can assess their students' acquisition of MIL skills.

However, promoting MIL skills among students and implementing them in their own teaching can be difficult for teachers to achieve on their own even if they themselves might possess these MIL skills. Progressing from being media and information literate to knowing how to embed MIL in pedagogical practices requires support at various institutional levels, from teacher training for pre-service teachers, to professional development for inservice teachers or educators in non-traditional educational settings. In order to address the growing need for teacher training in media literacy and information literacy (Martens, 2010), a UNESCO international expert group working on the MIL framework suggested that there is an important need to understand teachers' conceptions of media and information literacy (Pérez Tornero, 2008). While a number educational reform initiatives, such as the Next Generation Science Standards in the United States or the computer science curriculum in the United Kingdom, have recently integrated MIL-related concepts in their student

standards, implementing MIL in teacher education and teacher professional development may require time and institutional changes. The following section offers recommendations that educators can flow on their own as a first step towards the goal of promoting MIL to their students.

RECOMMENDATIONS FOR EDUCATORS

Given the current focus on implementing MIL in educational settings, it is critical that teachers understand and adapt to 21st century media and information in order to prepare learners to use technology in their personal, academic, and future professional lives. The following set of recommendations represent active steps that educators can take in order to accomplish that goal.

1. MIL is an attitude. Encourage your students to habitually question the information they encounter in their daily lives as well as the media through which the information is conveyed.
2. MIL is a literacy that transcends types of communication (e.g., books, radio, television, social networks). Practice it with your students both with traditional and new media.
3. MIL is knowledge about how information is transmitted. Teach your students how information is passed on through different media forms.
4. MIL is an investigative activity. Show your students the necessary steps to access and retrieve information based on their needs.
5. MIL is awareness. Help your students develop an awareness of how traditional and digital media providers transform and distort information to convey specific messages.
6. MIL is an evaluative skill. Model to your students how they can assess the veracity of information transmitted through different media.

7. MIL is creative. Encourage and guide students' creation of media to participate in their digital culture of interest.

In addition, organizations such as the International Society for Technology in Education (<http://www.iste.org/standards/ISTE-standards/standards-for-students>), and the Partnership for 21st Century Skills (http://www.p21.org/storage/documents/P21_framework_0515.pdf) further explicate some of the MIL competencies that both students and educators should possess to successfully evaluate, use, and create digital information and media in the 21st century. We recommend readers to look at their standards in order to obtain a complete picture of the current landscape in MIL-related skills.

SUMMARY AND FUTURE DIRECTIONS

This chapter discussed the importance of media & information literacy for digital communication in the 21st century. It provided a brief history of the MIL concept, as well as a discussion of the competencies that compose MIL. We also explored the essential role that teachers play in teaching MIL skills in educational settings and presented recommendations for educators to take the first step in embedding MIL principles in their teaching. Overall, this chapter presented an adaptive set of competencies that will help individuals situate themselves within and contribute to today's digital culture.

Future directions should explore inclusion of MIL within computing concepts, which has been highlighted as an area of importance in the classroom by many scholars (Barr & Stephenson, 2011; Eisenberg et al., 2005; Felini, 2015; Hobbs & Jensen, 2009; Perkovic et al., 2010; Qualls & Sherrell, 2010; Thomas, 2004; Wing, 2006; Yadav et al., 2014). Specifically, future work in this field should examine how exposure to computational thinking constructs also develops students' MIL

skills. As discussed previously, future research should also help to better understand teachers' conceptions of MIL in order to identify potential challenges and barriers to its integration in teacher education and teacher professional development. Furthermore, future research should also look at the implementation and effectiveness of MIL trainings, such as the UNESCO curriculum for teachers; both at the institutional and the individual level. At the institutional level, research is needed to understand the role that the MIL curriculum could play in teacher education programs, either as a domain-general or as a domain-specific set of skills required of future teachers. At the individual level, studies should look at teachers' engagement with MIL on a personal level in order to understand teachers' attitudes towards embedding MIL in their teaching. These future directions will contribute to UNESCO's overall mission to promote MIL on a global level, while supporting learners' acquisition of these vital 21st century skills.

KEY TERMS AND DEFINITIONS

Competencies: A set of knowledge, skills and attitudes.

Computational Thinking: A way of thinking and solving problems based on computer science concepts.

Media: The diverse body of media technologies that reach broad audiences through mass communication.

Media and Information Literacy: The skills required to critically access and assess mediated information while understanding media functions in our daily lives.

Information: The facts or data conveyed or represented via various media.

Participatory Culture: A culture in which individuals are engaged with media instead of simply being passive consumers of information.

Twenty-First Century Skills: A set of skills that individuals need to succeed in the 21st century.

Nigerian Undergraduate Students' Computer Competencies and Use of Information Technology Tools and Resources for Study Skills and Habits' Enhancement

D

Adekunle Olusola Otunla
University of Ibadan, Nigeria

Caleb Okoro Amuda
University of Ibadan, Nigeria

INTRODUCTION

Many educational institutions have adopted policies favoring the implementation of modern technology prompted by Information and Communication Technology (ICT). Modern technologies like the Internet, mobile tele-communication and World Wide Web (www) has become innovative tools that could engage students in continuous learning across homes, classes, campuses, offices, e.t.c. Thus, the role of technology using the Internet, cloud computing and networked computers in teaching and learning is turning teachers from providers of information to become facilitators of learning. As a result of technology-driven learning approaches there is a transition of teaching and learning communities from teacher-focused with traditional approaches to student-centered learning which is largely Technology-driven through the use of tools and resources that surpasses any other previous technology. Consequently, Davis (2010) affirms that technology integration within and outside the classroom is modifying the learning environment from teacher-centred to learner-centred with opportunities for personalized learning experiences. Bodys (2005) also reported that ICT tools and resources allowed students to be more individually active in the learning process and become more independent in making

decisions about how and what they need to learn using electronics learning resources.

Globally, different types of Computer-Based teaching and learning approaches have been developed to achieve the desired learning objectives and outcomes. Examples of computer technology applications, tools and resources for teaching and learning that cuts across all educational levels include; computer-assisted instruction (CAI), computer-assisted learning (CAL), e-learning, interactive video, multi-channel learning, virtual learning, virtual fieldtrips laboratories, virtual libraries, web conferencing, web chatting, digital story-telling, asynchronous online discussion (AOD) flip learning, e-mail communication and other forms of electronics and mobile learning among many other emerging learning technologies. Any of the listed technologies could be combined diversely into 'Learning Management Systems' (LMSs).

BACKGROUND

ICT integration among higher institution students particularly in Nigeria has attracted attentions through various studies. For example, Odusanya and Bamgbala (2002) reported ICT uses among final year students at the University of Lagos-

DOI: 10.4018/978-1-5225-2255-3.ch200

Nigeria; Jagboro (2003) reported on postgraduate students' use of the Internet to search for academic materials at Obafemi Awolowo University, Ile-Ife, Nigeria. Similarly, Ajuwon (2003) reported high rate of regular use of the Internet by medical and nursing students at the University College Hospital, Ibadan, Nigeria and Bello, Arogundade, Sanusi, Ezeoma, Abioye-Kuteyi and Akinsola (2004) also reported that a lower percentage of respondents demonstrated good knowledge of computers and IT at Obafemi Awolowo University Teaching Hospital, Ile-Ife, Nigeria. Ezekoka and Nwosu (2010) also reported that ICT has been found to be very useful in the teaching and learning processes among Nigerian students because of the extensive capacity to store and manipulate information as well as its unmatched ability to serve simultaneously many individual students in different locations as supplementary to classroom instruction. While writing of ICT policy framework, Adomi and Kpangban (2010) observed that the National Policy on Education (Federal Republic of Nigeria, 2004) recognizes the prominent role of ICTs in the modern world and advocated for its integration into the Nigeria educational system especially at the post primary and higher education levels.

Further, Otunla (2013) also stress that educational planners in Nigeria have seen the need for innovative instructional materials and media integration into the school system at all levels of Nigerian education. Adeoye (2013) noted higher institution students can learn through a virtual classroom environment where they can compose e-mails to conduct research via the Internet. The author further observed that the influence of technology on teaching and learning is enormous and could increase to an unimaginable and unpredictable level as new innovations are being introduced to the school system. Otunla and Baiyelo (2013) also observed that computers and Information Communication Technology (ICT) tools and resources such as the Internet, multimedia design, digital motion pictures, digital photography, web broadcasting; and digital print-

ing, teleconferencing, video-conferencing e.t.c. have greatly influenced mode of transaction and the way people relate in the last one and a half decades. Therefore, ICT has permeated every aspect of human existence because it has become an indispensable tool for daily living and especially the educational system. Otunla and Akinyemi (2014) noted that application and integration of mobile technologies in higher education could enhance effective communication between lecturers and students within and outside the four walls of the classroom. More recently, Ezekoka (2015) conducted a survey involving a sample of sixty lecturers in a Nigerian public university on availability of ICT facilities that could promote collaborative learning to increase the level of students' online participation. The author presented some problems encountered by the participants which hindered their optimal performance in online collaborative learning.

At the continental level Uys, Nleya and Molelu (2004) based on an outcome of three case studies of technological adoption within the African continent and abroad suggested that technology needs in Africa could be implemented within a combination of strategically developed framework for technology innovation diffusion. Subsequently, Mtebe, Dachi and Raphael (2011) from their findings on use of technology to improve teaching and learning outcomes in higher education, identified two key issues which are; the need to address problem of university teachers' readiness to accept change in their belief-system about teaching and the use of technology, as well as barriers to access required technologies in terms of hardware and software. Further, Nagunwa, and Lwoga (2012) enumerated some initial challenges faced in their university while they made an attempt to implement computer-based curricula by adopting e-Learning approach and presented the strategic re-establishment of an e-Learning approach. Therefore, it is glaring that higher institutions in Nigeria and African continent at large are taking advantage of the digital media and technologies to support and restructure their mode of teaching

and instructional delivery to prepare students for the world-of-work.

However, computer literacy and skills development are very crucial when it comes to integration of Information Technology (IT) tools, applications and resources in higher education. Without IT competencies and confidence in computer skills students' learning and research opportunities are very limited. Thus, acquiring basic skills in computing and communication media technologies by students is very essential in order for them to function in their academic activities, engage in personal studies and active learning using new technologies. Mcmillan (1996) identified the following characteristics of computer literacy, which connote that the individual; knows how to use: word processing software, an e-mail and a browser for Internet navigation and is capable of; registering or downloading information on at least an auxiliary storage or some other external saving units, recuperate information and print it elsewhere. Stein, Craig and Scollary (1997) further corroborate the need for functional definition which is tailored toward behavioural 'competencies' the authors added a cognitive dimension which defines computer competencies as; the ability to use ICT to identify and search efficiently for specific information in order to build knowledge and develop critical and creative thinking.

Another related technology skill required for knowledge deepening and knowledge creation is 'information literacy' (IL). The College of Dupage Library (CoDL) defines information literacy as the ability to locate, evaluate and use effectively the needed information (CoDL, 2002). Information literacy is also regarded as the set of skills needed to locate, retrieve, analyze and use information. Such that Andretta (2005) made a comparison of standards that was tagged 'Information literacy standards: A practioner's guide' as proposed by various agencies, organizations and professional bodies on skills that people must master before they will be able to perform all the necessary functions to become information literate. The organizations include; American Library Association (ALA),

Association of College and Research Libraries, Society of College, National and University libraries (SCNUL) and Australian and New Zealand Institute for Information Literacy (ANILIL). King (2007) also argues that the attributes of information literacy are multi-dimensional such that it involves employment of both traditional and modern information technology skills to retrieve, manage and present information in an ever widening array of information sources. Therefore, tertiary institution students must become information literate for them to be able to handle acquisition, management and analyzing large quantities of information and data that are widely available from different sources and more importantly from the Internet and the World Wide Web (www). Consequently, as earlier observed students and Internet users generally, need some special computer skills and competencies to be able to handle more effectively the ever-increasing digital information that could be annexed for educational purposes.

STATEMENT OF THE PROBLEM

As a result of the growth in the modern communication technology, and the need for today's higher education learners to become life-long learners through the use of IT tools and resources in preparation for the world-of-work. Moreover, IT is changing the role of tertiary institution students from that of passive-learners to active-learners within the learning environment, so as for them to keep up with current information and trends in their future professional practices. However, computer competencies and skills in the effective use of IT tools, applications and resources becomes a vital ingredient for students' digital mastery, active participation and visibility on the World Wide Web. Further, students are required to be technological-capable in the use and application of IT tools and resources that are abundantly available via the superhighway. Therefore, this chapter, investigate the computer competences and use of information technology

tools and resources in enhancing study skills and habits among undergraduate students in Rivers State, Nigeria.

RESEARCH QUESTIONS

1. What is the level of computer operational skills and competencies of undergraduate students in River State, Nigeria?
2. What is the level of competencies in the use of Information Technology applications and tools among undergraduate students in River State, Nigeria?
3. What is the extent of undergraduate students' use computer tools and software applications as part of their personal learning activities?
4. What is the extent of undergraduate students' use of Information Technology tools and resources as part of their personal learning activities?
5. What is the pattern of undergraduate students' computer competence in Information Technology tools and resources in relation to study skills and habits enhancement?

METHODOLOGY

The study adopted Ex-post facto research design of survey type:

- **Population:** The population of this study was undergraduate students in Rivers State, Nigeria.
- **Sampling Technique and Sample:** The study involved a sample of four hundred and fifty (450) undergraduate students were randomly sampled from three Universities with 150 undergraduate students each from Rivers State University of Science and Technology, Ignatius Ajuru University of Education and University of Port Harcourt all located in Rivers State, Nigeria.

- **Instrumentation:** Three researcher-designed validated instruments were used for data collection. Each of the instruments contains; (A) demographic information section in addition to section (B) that contains items measuring the variables of interest i.e. computer competency, ICT tools and resource use and study habit enhancement. They are:

- **Undergraduate Students' Computer Competency Questionnaire (USCCQ):** It contains a-25 item on computer competency with 3-point Likert scale ratings of 'Highly Competent' (3), 'Slightly Competent' (2) and 'Not Competent' (1).
- **Undergraduate Students' Information Technology tools and resource Use Questionnaire (USITRSQ):** It contains a 25-item on use of ICT tools and resources with 3-point Likert scale ratings of 'Regularly' (3), 'Rarely' (2) and 'Never' (1) respectively and lastly,
- **Undergraduate Students' Information Technology Study Skills and Habit Questionnaire (USITSSHQ):** A 30-item undergraduate students' use of information technology tools and resources to enhance study habit with 4-point Likert scale response options, of Strongly Agree (4); Agree (3); Disagree (2); Strongly Disagree (1).

The three instruments were trial-tested for validation on a group of students who were not part of the sample for the study; using Cronbach Alpha reliability test. The following values were recorded; USCCQ - $r=0.75$, USITRSQ - $r=0.70$ and USITSSHQ - $r=0.62$. The reliability values were considered to be valid and acceptable for the study.

Method of Data Collection and Data Analysis Technique

Primary data was collected directly from the sample covered in the study at the three higher

Table 1. Mean rating on level of computer operational skills and competencies of undergraduate students in Rivers State, Nigeria

Items	Mean	SD	Decision
Starting a computer	2.3384	.78055	*
Launching an application software e.g. Microsoft Word, Excel, etc.	2.6237	.62224	*
Typing document using Microsoft (MS) Word,	2.6667	.67879	*

Competency level was set at 1.50 and above, while Incompetence was set at 1.49 and below. Thus, '*' implies competent and '#' implies Incompetent on the decision column.

institutions located in Rivers State, Nigeria. Mean ratings and standard deviation; as well as analysis of variance (ANOVA) and regression analysis were used to answer the research questions.

RESULTS AND DISCUSSIONS

Research Question 1

What is the level of computer operational skills and competencies of undergraduate students in River State, Nigeria?

The grand mean score of 2.54 in Table 1 indicated that undergraduate students covered in this study were competent in using computer technology alongside IT tools, applications and resources in their knowledge formation, generation and acquisition. The finding implies that the undergraduates are active and creative in their quest to learn and acquire knowledge using digitally information systems to generate and gather

relevant information. Finding further implies that the undergraduates in Rivers State, Nigeria are compliant to the digital literacy in line with Mcmillan (1996) and Stein, Craig and Scollary (1997).

Research Question 2

What is the level of competencies in Information Technology applications and tools among undergraduate students in River State, Nigeria?

The grand mean score of 2.64 in Table 2 implies that undergraduate students in Rivers State Nigeria were competent in IT applications and tools alongside accompanying resources with the exception to Log in an e-mail account that recorded the least mean rating ($M=2.22$, $SD=.83$); this may not be unconnected with the fact that many undergraduates hardly operate institutional e-mails or maintain personal active e-mail, but depends on third party such as friends, cyber cafe and business centre operators. However, finding

Table 2. Mean rating on level of competencies in information technology applications and tools

Items	Mean	SD	Decision
Log in an e-mail account	2.2247	.83438	*
Composing e-mail communication	2.5126	.57133	*
Composing e-mail with attachment	2.6439	.57102	*
Sending e-mail with attachment	2.3965	.56648	*
Browsing educational information and resources using Universal Resources locator (URL) e.g. http// www.	2.4470	.62010	*
Browsing Journal articles	2.4798	.61796	*
Downloading e-book on Internet	2.7045	.62121	*
Downloading e-leaning document	2.5758	.71993	*
Downloading pictures on educational concepts	2.7096	.59022	*
Undertaking online application e.g. admission form processing	2.6995	.57200	*
Undertaking online registration e.g. course registration	2.6364	.61136	*
Submission of class assignment via e-mail	2.4419	.60308	*
Submission of class project via e-mail	2.6843	.55926	*
Grand mean	2.6429	.58736	*

Competency level was set at 1.50 and above, while Incompetence was set at 1.49 and below. Thus, '*' implies competent and '#' implies Incompetent on the decision column.

implies that undergraduate students in Rivers State Nigeria satisfied all the competencies highlighted by Mcmillan (1996) as well as Stein, Craig and Scollary (1997) on e-mail communications, Internet browsing and Information Technology.

Research Question 3

What is the extent of undergraduate students' use of computer tools and software applications as part of their personal learning activities?

The grand mean score of 2.32 as indicated in Table 3 implies that undergraduate students in Rivers State, Nigeria regularly engage in the use of computer tools and software applications in the course of their learning activities. Finding, further confirms that undergraduates in Rivers State, Nigeria are not only computer literate in line with Mcmillan (1996) and Stein, Craig and Scollary (1997) but are actively engaging in behavioural indicators that goes with such competencies

Research Question 4

What is the extent of undergraduate students' use of Information Technology tools and resources as part of their personal learning activities?

The grand mean score of 2.32 in Table 4 literarily implies that undergraduate students in Rivers State, Nigeria regularly use IT tools and resources as part of their personal learning activities and thereby technologically-capable. More so, they perceived themselves to possess information literacy skills needed to locate, retrieve, analyze and use information.

Research Question 5

What is the pattern of undergraduate students' computer competence in Information Technology tools and resources in relation to study skills and habits enhancement?

Table 3. Mean rating of extent of undergraduate students' use of computer tools and software applications as part of their personal learning activities

Items	Mean	SD	Decision
Starting a computer	2.1818	.65779	
Launching an application software e.g. Microsoft Word, Excel, etc.	1.9571	.73307	#
Typing document using Microsoft (MS) word,	2.4066	.59437	*
Slide preparation using MS PowerPoint	2.3283	.63110	*
Data input using Microsoft Excel	2.1818	.81894	*
Data analysis using Microsoft Excel	1.9040	.74350	#
Charts creation using Microsoft Excel	2.3258	.65406	*
Data input in power point	2.2121	.81471	*
Power Point slide show for group discussion	2.3696	.78701	*
Graphic design application tools in Corel Draw	2.3813	.68514	*
Creation of objects in Corel Draw	2.4798	.72363	*
Computer shut down processes	2.3384	.78055	*
Grand mean	2.3179	.6991	

High level of use was set at 1.50 and above, while low level of use was set at 1.49 and below. Thus, “*” implies high level of use and “#” implies low level of use on the decision column.

Table 4. Mean rating on extent of undergraduate students' use of IT tools and resources as part of their personal learning activities

Items	Mean	SD	Decision
Log in on e-mail account	2.3081	.60883	*
Composing and sending e-mail communications	2.5480	.67896	*
Composing e-mail with attachment	2.3283	.67378	*
Sending e-mail with attachment	2.4192	.63328	*
Browsing for educational information and resources using Universal Resources Locator (URL)	2.3409	.74115	*
Browsing for Journal articles	2.3561	.62601	*
Downloading e-book on Internet	2.3586	.66576	*
Downloading e-learning document	2.4672	.67613	*
Downloading pictures on educational concepts	2.4268	.69150	*
Undertaking online application e.g. admission	2.4394	.70719	*
Undertaking program registration e.g. course registration	2.3333	.77296	*
Submission of class assignment via e-mail	2.3763	.65784	*
Submission of class project via e-mail	2.1793	.71912	*
Grand mean	2.3179	.6991	

High level of use was set at 1.50 and above, while low level of use was set at 1.49 and below. Thus, “*” implies high level of use and “#” implies low level of use on the decision column.

Table 5. Summary of the regression analysis on the contribution of undergraduate students' computer and it competencies to study skills and habits enhancement

Descriptive Statistics			
Variable	Mean	Std. Deviation	N
Study Habits and Skills	83.7854	9.28872	396
Competencies	82.5859	7.61047	396

Table 6. Model summary and ANOVA

Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	4378.691	1	4378.691	58.084	.000
	Residual	29702.064	394	75.386		
	Total	34080.755	395			

R 0.358

R² 0.128

Adj. R² 0.126

SE 8.68251

Table 7. Relative contribution of predictor on criterion variable

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	47.655	4.761		10.010	.000
	Competence	.437	.057	.358	7.621	.000

Table 5 and Table 6 present the patterns of use of Information Technology tools and resources with the observed variance in students' study skills and habits which accounted for approximately 12.6% of the variance of student study skills and habits ($R^2 = .128$, Adjusted $R^2 = .126$). The result on ANOVA further indicated that pattern of use of IT tools and resources was a significant predictor of students' study skills and habits enhancement ($F_{(1, 394)} = 58.084$, $p = .000$). Table 7 reveals that the Beta values for pattern of use of Information Technology tools and resources ($\beta = .358$; $t = 7.621$, $p = .000$) was significant at .05 alpha level in terms of predicting student study skills and habits.

Findings establish the fact that undergraduate students in Rivers State, Nigeria are perceived to develop skills needed to locate, retrieve, analyze

and use information which partially demonstrates indexes of the College of Dupage Library (CoDL, 2002) definition which stated that information literacy is directly related to the ability to gather and assess relevant information as well as problem solving abilities. The pattern of use of computers and IT tools and resources which accounted for approximately 12.6% of the variance of undergraduate students' study skills and habits was a significant predictor that also agrees with the assertion of King (2007) on multi-dimensional attributes of information literacy, which employ traditional and modern information technology skills to retrieve, manage and present information.

Findings from this study further reveal that undergraduate student' competence and engagement in computer and Internet activities significantly contributes or enhances their

personal and study habits and skills. The finding partly agrees with the submission of Bodys (2005) on the ICT tools and resources allowed students to be more individually active and become more independent in making decisions about their learning.

FUTURE RESEARCH DIRECTIONS

Future research directions could be tailored towards ascertaining various information literacy skills among tertiary institution students in different parts of Nigeria which could be a large scale assessment using case studies alongside in-depth observational techniques.

CONCLUSION

In conclusion this study has revealed that there is no doubt that undergraduate students perceived themselves to possess competencies and skills needed to locate, retrieve, analyze and use information and that that information literacy is directly related to the ability to gather and assess relevant information using information technology tools. The pattern of use of computers and IT tools and resources to retrieve, manage and present information shows that higher institution students in Rivers State, Nigeria are technology-capable which invariably was perceived to enhance their study skills and habits

RECOMMENDATIONS

The study recommends that:

- Undergraduate students should take advantage of the opportunities provided by the Internet computing and Information and Technology for personal study and academic activities in preparation for the real world-of-work.

- University teachers and faculties in higher institutions of learning should integrate into their teachings such activities that compel students to engage in computer and Internet use as part of classroom interactions.
- Undergraduate students should sharpen their skills Internet computing so as to become more familiar with computer platforms, open source application, IT tools and OERs that could assist them their academic life both for their studies and research.

KEY TERMS AND DEFINITIONS

Information Literacy: Information Literacy is the ability to locate, evaluate and use effectively the needed information and it is also regarded as the set of skills needed to locate, retrieve, analyze and use information (The College of Dupage Library, 2000).

Information Technology (IT): IT is a broad term which covers all the aspects of the uses of computer technology which includes not only hardware and software, but also communication technology; linking computer systems, software engineering, administration and supporting the infrastructure to manage and deliver information (David, 2006).

The Roles of Digital Literacy in Social Life of Youth

INTRODUCTION

This chapter contains updated findings related to social aspects of digital activities of youth (Martinovic, Freiman, Lekule, & Yang, 2014). Computers, mobile devices, and the Internet are increasingly used in everyday social practices of youth. Recent statistics reveal that in September 2015, there were 1.01 billion daily active users and on average 894 million mobile daily active users of Facebook (Facebook, 2015). To be successful in school, work, and in socializing, youth need to competently use digital tools and define, access, understand, create, and communicate digital information. Being able to evaluate digital information, develop perceptions of, and respect for, social norms and values for functioning in the digital world, without compromising one's own privacy, safety, or integrity is also important. The competencies and skills that new generations require to be successful in the digital era are largely still not being taught in schools. Results of this chapter will provide the following:

- Address the social prospects of Information and Communication Technology (ICT) use among youth;

- Describe the online behavior of young people through the paradoxical nature of the Internet that provides opportunities for social development but introduces risks;
- Inform educators and youth services about which factors to consider in designing flexible, innovative, and inclusive programs for young people to enable them to successfully function in the era of the Internet, new media, and computer technologies.

BACKGROUND

In the past 15 years or so, ICTs became increasingly accessible in most countries. The ICTs like personal computers, cell phones, and the Internet can be used for both in-school and out-of-school activities, and are particularly suitable for connecting individuals and communities globally (Beetham, McGill, & Littlejohn, 2009). Using these tools appropriately so that one can live, learn, and work in a digital society, is broadly defined as being digitally literate (Beetham, 2010). However, by and large, these competencies and skills are not being taught in schools (Martinovic, Freiman, & Karadag, 2011). For

example, Jenkins (2006) finds that youth are not taught how to participate in social online practices (e.g., in information sharing and collaboration) despite dangers for unskilled users, whereas some authors (Martinovic & Magliaro, 2007; Noveck, 2000) emphasize importance of understanding a paradoxical nature of the Internet, where one can be confronted with limitless information, while obtaining less knowledge; where access is relatively cheap, but the environment is increasingly commercialized; and where communities do form, but atomization prevails.

Livingstone (2008) describes the dichotomy of optimistic and pessimistic opinions coming from academics and media on how ICTs affect young people:

- Optimists emphasize the new opportunities for self-expression, sociability, community engagement, creativity, and new literacies. They envision change in social dynamics, with youth involvement in the co-creation of innovative and counter-consumerist cultures both locally and globally. Public policy makers and educators see opportunities for engagement in collaborative learning and various online government services. Xie (2014), for example found that mobile communication through social networking sites, amplifies social capital of teenagers.
- Pessimists associate the behavior of youth on social networking sites with loss of privacy and lack of shame. They look at social networking as time-wasting and socially isolating activities that may have far-reaching negative effects on the safety of youth. Others fear that youth growing up in the digital age may be barren of understanding emotional nuances and reading social cues, and may lack empathy (Stout, 2010). They note that cyberbullying results in changes in behavior and deep emotional problems among its victims (Mitchell, Ybarra, & Finkelhor, 2007; Ybarra, Diener-West, & Leaf, 2007), and that the effects of Internet

communication both with peers and with strangers on well-being may be particularly adverse for lonely adolescents (Valkenburg & Peter, 2007). Patton et al. (2014) warns against increase of youth violence in on-line space, which includes cyber-bullying, -gangs, -stalking, and -suicide. Moreover, young people recognize that using the Internet for schoolwork may encourage taking shortcuts, cheating, laziness, low school morale, and may hinder development of study skills (Ben-David Kolikant, 2010).

Based on these examples, a digitally literate person should be able to navigate between opportunities and traps created by introducing different ICTs in one's everyday social life.

SOCIAL ONLINE PRACTICES OF YOUTH

Issues, Controversies, Problems

Current international statistics reveal that about 87.9% of North Americans, together with 73.5% Europeans use the Internet (Internet World Stats, 2014). Extreme growth in Internet use in Africa, Middle East, and Latin America in the last 15 years is measured in thousands of percent. Young Canadians seem to follow such common worldwide trends. One Canadian study, Young Canadians in a Wired World (Media Awareness Network, 2001-2012) looked at the online behavior, attitudes, and opinions of more than 5,200 children and youth from grades 4 to 11 in French- and English-language schools in every province and territory. The report revealed that in 2005, young Canadians were almost universally connected to the Internet through the household computer, personal computer, and/or cell phone, and were active users of the ICTs. While the participants in this study described their online experiences as generally positive and socially rewarding, they also reported being exposed to inappropri-

ate content and risky situations such as bullying and sexual harassment which may compromise their integrity and privacy. For this reason the participants highlighted the need to learn how to distinguish credible from non-credible information on the Internet.

In the further text we address the issues of formation of identity, friendship, participatory culture, and political engagement in the context of the ICT use. These areas of social development of young people are described in the literature as dependent on their age.

Identity Formation

Pre-School and Primary School Children

At the very young age, children discover virtual world when playing. Aguiar and Taylor (2015) investigated how preschool children would differentiate the social affordances of a virtual character that simulates social behaviors and those of a stuffed animal they used to play with. It was found that the children relate to the stuffed dog as a friend, while the virtual dog, even when sophisticatedly programmed appear to be entertaining rather than the relationship partner.

Between ages 7-12 which we define as the stage of emerging digital literacy, digital life experiences of children are highly dependent on what ICT are available at home and in school. At the same time, access and use are restricted by parents, educators, laws, etc.

Use of Internet by 39 fourth-graders (ages 9-11) from a small New Hampshire town was studied by Henke and Fontenot (2007). The researchers found that the children were already veteran Internet users (i.e., having at least two years of experience) and that they were able to identify the persuasive intent of commercial Websites, and to distinguish between the informational and entertainment functions of non-profit and government Websites. The children were unwilling to substitute other social activities for Internet use, which was influenced by teachers, parents, and older siblings.

Adolescents

Issues of identity and privacy become even more important in the increasing socialization of youth aged 12-18. Hundley and Shyles (2010) conducted focus-group interviews with 80 West Coast and East Coast U.S. teenagers (ages 12-16) to ascertain their perceptions and awareness of digital technology. The authors learned that the Internet, and particularly social networking sites, played an important social role in the young people's lives: Cell phones helped them to connect to one another; computer games, to have fun; and social networking sites, to stay in touch and connected. Some geographical and cultural patterns emerged: While Facebook was almost unknown in the West (mostly Hispanic) and popular in the East (mostly white), MySpace was the overwhelming favorite among all participants (with West Coast youth more active). The number of online friends varied from 6 to 1000, averaging 85-200. Favorite activities on social networking sites were "talking/meeting with friends," "staying in touch," "updating profile," "checking other profiles," "checking messages," "texting friends," and "multitasking" (e.g., simultaneously using a computer, listening to the music, and watching TV).

For adolescents, electronic media were powerful socializing agents, but they did not completely replace other sources for social interaction. Hundley and Shyles's (2010) participants liked to combine face-to-face and online socializing; their online social groups mirrored their real-life communities. The participants were aware of online risk and saw the danger of cyber-attacks on their privacy, but were ready to accept the risk as they were careful not to disclose any personal information. However, some participants acknowledged they were occasionally dishonest when providing information on Websites (e.g., hiding their age), but did not see a problem with this.

Valkenburg, Schouten, and Peter (2005) surveyed 600 adolescents and found that the Internet plays an important role in their identity exploration and creation. The authors identified different self-

presentational strategies used by these youth. For instance, younger adolescents, girls, and extroverts significantly more often pretended to be older than did the older adolescents, boys, and introverts. Boys and introverts presented themselves more often as a macho person, whereas girls, younger adolescents, and extroverts presented themselves more often as a more beautiful person. Finally, boys presented themselves more often than girls as a real-life acquaintance or as a fantasy character.

Based on the focus group interviews with 127 Italian young Internet users (i.e., middle and high schools students of age 11–20), Bosca et al. (2015) concluded that adolescents do not speak favourably about people who on the Internet post their altered photos or lie about their appearance.

Harman, Hansen, Cochran, and Lindsey (2005) argued that misuse of the Internet can affect various aspects of children's social lives. Harman et al. conducted a study of 187 predominantly European or American sixth-, seventh-, and eighth-grade students, aged 11–16. The children who reported the most deceitful behavior on the Internet (e.g., pretending to be older) had poorer social skills, lower levels of self-esteem, higher levels of social anxiety, and higher levels of aggression (i.e., inappropriate assertiveness), regardless of gender. Frequent use of the Internet, however, did not affect the children's social skills, self-esteem, social anxiety, and aggression.

However, Livingstone (2008) noted a difference between how younger and older teenagers created their online profiles. Younger teens had a playful approach and created profiles that were decorative, stylish, and elaborate. Older teens, on the other hand, created plainer profiles that emphasized their relationships with others (e.g., links to their friends' profiles and group photos). The danger for this latter group lay in their lack of knowledge of when or how to draw a line between what to say in private and in public medium. In addition, Livingstone found that how the teenagers classified their friends (e.g., friends from school, friends from holidays, real friends, old friends, best friends, good friends, 'hi-and-bye' friends)

and the corresponding granulation of closeness with them were not adequately matched by the privacy features of the social networking sites (i.e., 'public' or 'private'). The author suggested that teenagers struggle with online privacy because of this mismatch between their needs and the features of the sites. Moreover, inadequate, confusing, or poorly designed site settings, along with the teens' limited Internet literacy, often left the teens unclear about their control over who could see what about them.

Nonetheless, as shown by both anecdotal and research evidence, youth are very protective of their digital spaces and they make a sharp distinction between situations in which they participate in formal learning and those in which they socialize and learn informally. For example, Marwick, Murgia-Diaz, and Palfrey (2010) argued that young people may not perceive the Internet as a public space. In many ways, "online spaces like MySpace and Facebook are seen as private social spaces where young people can engage in personal talk, gossip, 'hanging out,' flirting, sharing secrets, and all the other social practices that they engage in with their peers offline" (p. 61). From this perspective, youth have redefined the concepts of 'private' and 'public'; they want to keep some digital spaces private from the watching eyes of adults (be they parents, teachers, or marketers) so that they can freely socialize there under their own terms. This stand for also confirmed in Bosca et al.'s (2015) study, although the Italian adolescents also mentioned using Internet to connect to parents. The authors suggested that family relationships may benefit from the Internet communication between parents and children, as long as the parents recognize adolescents' need for autonomous use of online spaces and let them demonstrate their digital skills, which can also improve the status of their children in the family.

Recent study of online behavior of 11–15 year old youth conducted by Afshar et al. (2015) expresses concerns that when shifting to the online world, adolescents can develop social phobia which drives them to having a hidden identity,

while potentially damaging their natural and real identity.

Internet use by adolescents with developmental and social differences was explored by Bannon, McGlynn, McKenzie, and Quayle (2015). The authors conducted focus groups with 36 young people (aged 13–18) who were all identified with Autistic Spectrum Disorder, moderate learning difficulty, and/or social, emotional and behavioural difficulties. Bannon et al. identified aspects of development of identity, social connectedness, and competence (e.g., in specific skills as well as a sense of self-competence) through their participants' use of the Internet. These individuals not only developed in these three areas, but purposefully used the Internet to build social ties to others and avoid sense of anxiety of offline communication. While this segment of adolescent population used the Internet in a similar way and with similar benefits as youth in general, they may need some extra measures to be put to ensure their online safety.

Young Adults

Mahiri (2004) described how youth nowadays use electronically mediated popular culture to produce, consume, and propagate personal/cultural meanings, individual pleasures, and desires that inform, challenge, and often counter well-established societal norms and forms. One example can be seen in Seibel-Trainor (2004), who described a case of a college-educated, single young woman, a member and a regular contributor to The Gossamer Project, who described herself as a “media junkie” (p. 127) who spent 2-5 hours a day reading and writing for The Gossamer Project. This woman, Barbara, followed the events and characters from the series, and as other fans on the Website did, wrote about them extensively. Barbara produced character studies, wrote commentaries on each episode, and predicted what would happen in the next episode. She posted her stories about main characters from the series and received her own fan mail. This was all done under the scrutiny of the television network, which tried to block

the writing of fans like Barbara. However, this attempt of the TV network generated strong opposition from the fans, who organized a maze of connections from their personal Web pages to the Gossamer Project Website to protect Gossamer Project contributors from intellectual property lawsuits. Seibel-Trainor concluded that the Internet removes the distinction between the writer and the reader; writers like Barbara write for their cyber-friends and other fans; they do not accept simply being consumers of media.

West, Lewis, and Currie (2009) interviewed 16 undergraduate students, 21-26 years old, who reported having on average 82 real-life and 200 Facebook friends. All participants had more friends on Facebook than in real life. Facebook friends consisted of real-life friends, cousins, and friends of friends, all of whom were of similar age to the respondents. The students generally did not like the idea of having parents as friends on Facebook, and some were even happy that their parents did not know how to use the Internet, thus allowing them to keep the details of their social life private from their family. The authors suggested that youth who participate in social networking sites have a different notion of what is private and what is public, a distinction that cannot be described in a clear-cut binary way.

In summarizing research on new media spaces, Zemmels (2012) took a stance that nowadays, “identity is largely constructed through media engagement” (p. 17). From that perspective, the construction of identity happens through the active use of media where young people do not only consume, gather, and distribute media content, but add their personal voice in producing media. This creates ‘new social operating system’ where “networked individuals” are constituted within “networked publics,” and where ICT increasingly shape social practices (Zemmels, 2012, p.17).

Redefinition of Friendship

Social networking sites provide increasingly more attractive functions to their users. A well-

developed Facebook or MySpace profile provides a look into the owner's life in a way that the person wants to be perceived by his or her peers (Maranto & Barton, 2010). Users normally search for those who share their labels and/or interests, and request to add them as 'friends.' Through this snowball effect, an individual can quickly become part of a network of many friends.

Intensive engagement of youth in electronic communication, such as texting, instant messaging, and Internet chats, influences the development and expression of their emotions. Some authors (see Stout, 2010), caution that due to the declining of face-to-face communication within the electronic age, the younger generation may lack exposure to real-life experiences that help them develop empathy, understand emotional nuances, and read social cues like facial expressions and body language. As a result, for today's teenagers and preteens, friendship is apparently realized through the exchange of cell phone texting and instant messaging, or on Facebook walls and MySpace bulletins. There are also some noted gender differences in use of the social networking sites—girls use such sites to reinforce pre-existing friendships, whereas boys use them to flirt and make new friends (Lenhart & Madden, 2007); technology is changing the nature of young people's friendships.

However, after Mesch (2009) conducted a survey with around 1,000 adolescents in Israel, he concluded that the youth seem to maintain two separate networks of online and off-line relationships. The type of communication channel adolescents used mostly depended on the strength and origin of social relationship between them. Those who first met face-to-face, who lived in each other's vicinity, and who felt that their relationship is strong and trustworthy, preferred to communicate directly, face-to-face and over the phone.

Participatory Culture

The Internet has shattered the traditional hierarchical boundaries between producers and consumers

of information. Nowadays, millions of youth are both reading and creating material posted on Websites related to topics of their interest. For Jenkins (2006), this type of engagement presents an example of a participatory culture where young people become actively involved in constructing their own virtual spaces from which they can critically examine the real space of adults. Social networks' participants "are also becoming active producers of new media and distributing them in global networked publics" (Zemmel, 2012, p. 17).

In an attempt to find overlaps/connections between online and offline youth cultures, Wilson and Atkinson (2005) investigated how the Internet has been integrated into the everyday subculture of Canadian youth. After analyzing two cases, the 'Rave' and the 'Straightedge', the authors concluded that the Internet is used as a device for bringing people together in real time and as an enabler of subcultural resistance. For example, music has a particular strong bonding role in youth communities; it is useful in providing group identity and in promoting a distinct lifestyle. The availability of various media formats, such as MP3 or MPEG audio files placed on Websites for free download play a great role in this matter. Various social groups, formally labeled by the mainstream culture as misfits, succeed in winning a cultural space, albeit a virtual one. Wilson and Atkinson concluded that youth culture in the age of the Internet could be viewed not only as "more fragmented, diffuse, and neo-tribal than traditional subcultures...but also as more cohesive in the sense that virtual connections can enhance local relationships" (p. 305).

Political Engagement

Through social networking Websites (e.g., Facebook, MySpace), youth are emerging as important factors in political and social change. In their study of 1875 middle-school students from Hong Kong, Seoul, Singapore, Taipei, and Tokyo, Lin, Cheong, Kim, and Jung (2010) investigated youth engagement with social issues. The researchers

found that about half of the teens read news on the Internet, visited charity, environment, or government Websites, voted to reflect their opinions, and/or signed a petition online (one in five youth). While teens preferred to use these virtual spaces to discuss entertainment, sports, or shopping, social networking sites also served as “potential mobilizing forces” (p. 852). For youth who are already interested in politics and are civic-minded, the Internet may function as an amplifier of engagement, albeit in “unconventional ways” (p. 843).

However, Lin et al. (2010) also referred to other researchers (e.g., Livingstone, Bober, & Helsper, 2004) who noted that the U.K. teens they studied had little interest in political engagement on the Internet because they thought it was not very likely that politicians would ever listen to them. Yet Livingstone et al. (2004), too, found that 54% of the teens had visited either charity, government, environment, and human rights sites or Websites for improving conditions at school or work.

Nowadays, youth are involved in international groups where they discuss and organize events related to environmental (e.g., the Earth Hour) and political (e.g., Relay For Life) causes. In other words, youth deploy the technology to spread their political and social views, promote environmental awareness, and raise funds for their favorite causes or charities (Maranto & Barton, 2010). Still, as Wilson and Atkinson (2005) pointed out, violent confrontations between individuals and groups at public spectacles also get arranged in advance through the Internet. Also, students who are influenced by the existence of social peer in-groups in their schools (e.g., geeks, jocks, fashionistas) may take the same exclusionary attitude on the Internet and resist connecting with those who belong to groups other than their own.

SOLUTIONS AND RECOMMENDATIONS

Whatever we say and write about the youth and their habits, connectivity remains the key, which has led some authors to name them the connected

generation (Mason & Rennie, 2006)—that is, the generation that is involved in a wide spectrum of online activities, including buying online. While the positive attributes of connectivity are well recognized, the authors see it also as a trap, especially for youth; instant messaging could be a distraction to learning, extensive use of chats and multiuser discussions could be associated with impaired academic achievement and social isolation, as well as privacy could be lost through providing access to personal data to unintended recipients.

Providing solutions and recommendations is problematic, as digital literacy phenomena are quickly changing, as the ICTs and practices that surround them change. Davies and Cranston (2008) proposed using social networking sites as tools to encourage youth to become more socialized and to learn something informally. They acknowledged, however, that “something” learned may well be undesirable, ranging from relatively benign commercial advertisements to content that does not contribute to healthy social and cognitive development. Thus, young people need supports in developing “appropriate skills and resilience to navigate online social networking risks and opportunities” and developing “shared understandings of safe and reasonable online behaviour patterns” (p. 3). This suggestion extends beyond the simple blocking of social networking sites and instead encourages working with youth as an alternative. In a recent paper, Vodanovich et al. (2015) point at the lack of holistic approach to fully grasp the impact of social networking sites on digital natives’ well-being, in particular their social competence. The authors point at an important role that ubiquitous spaces play in a complex processes of youth becoming independent from their parents, gaining social acceptance from their peers and establishing a coherent identity. Hence, the role of adults is to understand, appreciate and in turn support digital natives in making the all-important transition to adulthood within this new environment.

FUTURE RESEARCH DIRECTIONS

Our work has allowed us to identify issues related to youth's understanding and respecting online social norms and values. But these issues easily become more complex and subtle when we take into consideration meta-social skills (identity formation, friendship, self-esteem, autonomy, etc.). We found that technologies do affect the development of well-rounded citizens of modern society in different ways, and that this development is not easy to capture and assess because no ready-to-use and evidence-based developmental frameworks exist. There is a conceptual and methodological gap between the need for such frameworks and reliable data available to support their development and validation across cultures, age groups, social groups, and individuals.

CONCLUSION

Young people nowadays face challenges that require development of healthy social behavior with regard to online identity formation and protection of privacy. Some positive aspects are seen in the rising of a participatory culture among youth, whereby they use virtual spaces to critically examine the real space of adults. Youth subcultures emerge, and often-marginalized youth find ways to exercise creative expression and shape their own identity. Moreover, the ICTs allow young people to emerge as legitimate social and political actors. Using unconventional ways of engagement, young people surface as political beings and as individuals interested in civic and environmental issues. Some ICT-related addictions (e.g., to computer games, to Facebook, to text messaging) may disappear on their own, while for some problems, interventions may be needed. For example, adolescents may spend less time playing computer games when they start developing an interest in dating and socializing face-to-face. It seems that youth need to be

educated about the importance of maintaining a balance between their real and virtual lives. Organizing outings and clubs where youth play, compete, and socialize may counteract to some extent the allure of the technology that youth are exposed to.

KEY TERMS AND DEFINITIONS

Active Users of the ICTs: Individuals, groups and organizations that utilize e-mail, instant messaging, chat rooms, access and download media content, write blogs, and play online games.

Developmental Stages of Digital Literacy in the Social Domain: Stages through which an individual, over time, acquires the digital literacy skills necessary to be considered competent at using digital tools and at defining, accessing, understanding, creating, and communicating digital information.

Digital Literacy (as a Complex Term): One of many constructs that involve the word “literacy”; it includes elements drawn from information literacy, media literacy, and visual literacy.

Digital Literacy (as Ability): Ability to use digital technologies appropriately for learning, working, and functioning in a modern society.

Information and Communication Technologies: ICTs include personal computers, laptops, tablets, PDAs, cell phones, smart phones, computer networks, and the Internet.

Information Literacy: Emphasizes the need for careful retrieval and selection of information available in the workplace, at school, and in all aspects of personal decision-making, especially in the areas of citizenship and health.

Media Literacy: Ability to decode, evaluate, analyze and produce both print and electronic media.

Participatory Culture: A culture in which artistic expression and civic engagement are valued, oriented towards creating and sharing one’s creations.

Social Capital in Online Communication: Social capital developed through online activities and participation in online social networks (e.g., text messaging, chatting, content sharing, organizing group activities, commenting, and tagging).

Social Capital: Quality of group membership. Measured by for example, the frequency of face-to-face interactions with close friends, the number of offline acquaintances, sense of loneliness or lack thereof, community involvement, civic and political participation, and interpersonal trust.

Visual Literacy: Ability to see, discriminate, and interpret the visible natural or artificial objects and symbols in the environment.

Toward a Working Definition of Digital Literacy

Margaret-Mary Sulentic Dowell
Louisiana State University, USA

INTRODUCTION

Digital literacy (Alkali & Amichai-Hamburger, 2004; Bawden, 2008; Buckingham, 2006; Gilster, 1997) is a broad, umbrella term that pertains to the use of literacy skills defined as reading, writing, listening, speaking, composing, communicating, and interacting within digital environments. For example, accessing information and sending information via the internet such as viewing and posting YouTube videos or creating, sending, and receiving e-mails is digital literacy. As well, anime, manga, blogging, fandom blogging, texting, tweeting, designing memes, sharing headcannons, and other forms of creating ideas and communicating perspectives through social media platforms such as Facebook, twitter, Tumblr, and myriad others ways to share thoughts and opinions over the internet or in cyberspace, all qualify as digital literacy (Beach, 2012; Black, 2005; Booth, 2012; Martin & Madigan, 2006; Kist, Tollafield, & Dagistan, 2014; Rodesiler, 2015).

Also referred to as *new literacies* (Coiro, Knobel, Lankshear, & Leu, 2007; 2008; Hagood (2009), Knobel & Lankshear, 2014; Lankshear & Knobel, 2006; Street, 1998), digital literacy implies both the technical ability and emotional skill level needed to generate thought and communicate in multiple formats within digital environments (Elshet-Alkalai, 2004; Landham, 1995). In particular, both the consumption and generation of text and the practices used to create and consume them, formally and informally, both outside and within school, broadly define new literacies. According to Hagood,

New literacies consist of several characteristics: (1) multimodalities, which include linguistic as well as visual, gestural, and auditory texts, (2) situated social practices, which are culturally, linguistically, and textually based, and (3) identities, which connect text users to text uses. (2009, p. 1)

BACKGROUND: A WORKING DEFINITION OF DIGITAL LITERACY

Digital literacy is a complex combination of skill sets defined as the knowledge, technical skills, use, actions, and behaviors that individuals utilize with existing myriad digital and technological devices and resultant forms of communication that have become an integral part of so many people's daily lives. For instance, every day use of a cellphone, smartphone or perhaps a tablet involve digital literacy skill sets. Thus, digital literacy implies the mastery of both the tools and embedded use of technology in personal lives. Digital literacy is also the recognition that digital forms of literacy and the aforementioned skill sets play an essential, critical role in educational and work settings, particularly the reasoned awareness regarding the content that is created and its use in digital literacy formats. Lanham (1995) argues that the notion of being literate has extended from the ability to read and write, speak and listen, to the ability to understand information that is available and accessible in multimodal ways. Being literate in the 21st century requires being skilled at interpreting complex images and discerning the "syntactical subtleties of words" (Lanham, 1995,

p. 161). Whereas historically literacy has included the notion of both composing and comprehending language, defined as the ability to speak, listen, read, and write, literacy has evolved to include a “social practices” approach from scholars within the emerging educational field of New Literacies (Barton, Hamilton, & Ivanic, 2000; Gee, 2001; Street, 1993).

Similar to Lanham, Alkali and Amichai-Hamburger (2004) provide an inclusive, comprehensive definition of digital literacy specifically referring to much more than the ability and skill needed to simply use and navigate a digital device or software, rather, digital literacy requires complex thinking skills as well as critical decision-making ability. The kind of multifaceted thinking required of digital literacy equates to the knowledge beyond how to operate digital devices, access information, or utilize software and refers to the complicated cognitive abilities, requisite motor skills, as well as the sociological and emotional maturity needed to navigate digital environments effectively, usefully, and appropriately. A conceptual model detailed by the authors proposes that digital literacy encompasses five essential digital skills: photo-visual skill – gaining understanding from graphic displays of information; reproduction skill – wherein individuals employ digital reproduction expertise to recreate or craft innovative, significant materials from pre-existing materials; branching skills – defined as building and fashioning knowledge from non-linear, hypertextual navigation); information skills – both assessing and gauging the quality and legitimacy of information), and socio-emotional skills – the mindfulness of the tacit rules that exist and are in place in cyberspace and being able to apply this awareness in online cyberspace communications (Alkali & Amichai-Hamburger, 2004).

Expansion of Digital Literacy

Digital literacy has significant implications for society as a whole and for learning and teaching specifically as new forms of communicating

become the norm (Davies & Merchant, 2009; Gilsten, 1997; Hunter & Caraway, 2014; Pool, 1997). As a practical illustration of what was once a new form of communication becoming the norm, twenty years ago, most households in the United States (US) had landlines. Currently, many US homeowners have discontinued a landline and exclusively use a cell phone. In fact, the various platforms and constructs of social media for the current generation of students equates to most students using at least one form of social media as part of their daily lives (Jenkins, 2006; Lapp, Fisher, Frey, & Gonzalez, 2014; New Media Consortium, 2007). These students will matriculate to a career and the work force, taking with them the expectations of using digital literacies.

As an example of the burgeoning use of digital literacy, Rideout, Foehr and Roberts, assert that, “Eight to eighteen-year-olds spend more time with media than in any other activity besides (maybe) sleeping—an average of more than 7½ hours a day, seven days a week.” (2010, p. 1). Rideout, Foehr and Roberts surveyed a nationally representative sample of 2,002 3rd–12th grade students, ages 8–18 in the US, which contained a subsample of 702 respondents who voluntarily completed week-long (seven-day) media use diaries. Conducted from October 20, 2008, through May 7, 2009, they report that 8 to 18 year olds were spending approximately 6.5 hours with media (cell phones, internet, television, gaming, music) but because these students were adept at multitasking, they were engaged in closer to 8.5 hours of media content daily. According to the authors, based on a survey sample from 2005 to 2010, young people between the ages of 8–18 increased their media consumption by an hour and 17 minutes to 7.5 hours daily, the average work day for most adults. Considering that adults tend to work 40 hour weeks within a five day span, the consumption detailed in Rideout, Foehr & Roberts’ work, represents an incredible amount of time spent with digital literacy. Clearly, the research of Black, (2008), Jenkins (2006), Lapp, Fisher, Frey, and Gonzalez (2014), the New Media

Consortium (2007), Rideout, Foehr & Roberts (2010), and Squire (2008) highlight the pervasiveness of digital literacy practices and depth of participation within a specific segment of US population. Researchers in the United Kingdom (Martin & Madigan, 2006; Street, 1984), Canada (Gilster, 1997), the Netherlands (Kuiper & Volman, 2008), and Australia (Lankshear & Knobel, 2006; 2008; 2012; Ng, 2006; 2010; Thibaut, 2015) also investigate the meaning, use, and prevalence of digital literacy, and postulate that expanding usage will occur and rapid developments will be accessed by younger and younger consumers of digital literacy. The implications for society at large are significant.

DIGITAL LITERACY WITHIN A SOCIO-CULTURAL FRAMEWORK

As an overarching framework, Russian theorist, Vygotsky's (1978) sociocultural theory of learning and the social nature of learning coupled with the mediated aspects of human learning situate the discussion of digital learning. Vygotsky's view of learning is rooted in the social interactions between people and resultant learning that may occur, referred to as the zone of proximal development. French theorist Baudrillard (1990), provides a compatible framework based on his notion of media and culture in the ways that technological progress affects social change. Both Vygotsky and Baudrillard focus on social interactions, providing a link to the powerful ways digital literacy is situated in socio-cultural environs.

Similarly, the work of Beach (2012) and Hagood (2000) informs the perspective that learning is situated, occurs within a socio-cultural context that is meaningful to the learner(s), and not confined to classroom walls and school. Each advocate for literacy that is social, collaborative, and relational, requisites of digital literacy.

Drawing upon the work of Project Tomorrow (2012), Beach addresses the outside versus inside school contexts of leaning, supporting learning

as social activity and occurring in environments that are meaningful and constructed by learners. Beach confronts a "false binary between uses of digital tools for school and non-school social purposes, adolescents are increasingly adopting tools to support their learning." (2012, p. 46). According to Beach, real differences between in and out of school literacy points to students engaging in reading and writing within schools to fulfill graded assignments versus reading and writing outside of school as opportunities for both self-expression and identity construction as well as a social communication activity and seeking specific information that is personally meaningful. The social aspect of students' literacy outside of school is rooted in socially-constructed communication, and essentially addresses primary constructs of writing – audience and purpose – first established by Graves (1983). In essence, Beach confronts the notion of informal learning, learning marked by where it occurs, challenging the less than perception of where learning and literacy occurs and for what purposes.

Hagood (2000) argues that the literacy practices that occur outside of formal schooling are equally important as those that are practiced within formal schooling. Perceiving an evolving literacy landscape that encompasses digital literacy forms and formats, Hagood explicates how literacy is at a crossroad, acknowledging traditional views of literacy that are socio-cultural in nature but maintaining that new literacies are evolving into deep social practices that emphasize social and cultural relationships.

In many educational contexts, social media is a viable means to engage students in their learning creating possibilities to collaborate and offering opportunities to connect with peers; the digital literacies afforded by social media also provides ample opportunity for informal learning (Beach, 2012; 2012; Jenkins, Clinton, Purushotma, Robnson & Weigel, 2007; Junco, Heiberger & Loken, 2011; Kilinc, Evans, & Korkmaz, 2012; Lanksher, 1987; Street, 1984; Thibaut, 2015). In fact, there is a long tradition of literacy practices

wherein communicating effectively with others in meaningful ways is situated outside schools and traditional modes of learning (Heath, 1983).

NEW LITERACIES, NEW ISSUES: THE DIGITAL LITERACY IMPACT

Situated within the field of education, three prominent digital literacy issues have surfaced. Those issues are:

1. The dissonance between digital natives and digital immigrants,
2. Some forms of digital literacy enjoy acceptance and legitimacy, and
3. Access to digital literacy formats.

Digital Native or a Digital Immigrant?

Digital natives or the E-generation (Jones & Flannigan, 2006) and digital immigrants, oftentimes identified as baby-boomers and the generations of adults who grew up in a world of print media (Jones & Flannigan, 2006), are defined broadly as those who have acquired digital literacy skill as children versus those who have acquired digital literacy skill in adulthood (Anderson, 2002; Bennett, Maton & Kervin; 2008; Jones & Flannigan, 2006; Prensky, 2001). This is a generational issue regarding when within a lifetime literacy is acquired and is noteworthy.

Prensky (2001), credited with coining the terms digital native – digital immigrant, posits that education must keep pace with the rapid evolution and expansion of digital literacy in order to adequately prepare children for careers and a workforce that will expect sophisticated forms of digital literacy knowledge and skill. Prensky illustrates the dichotomy of traditional teaching practice with the demands of digital literacy which will continue to evolve and expand, calling for a reassessment of literacy teaching and learning.

Generational shifts in literacy acquisition, increasingly sophisticated information processing, and rapidly evolving forms of digital literacy

uniquely impacts teacher preparation. In essence, 21st century teacher preparation programs and teacher educators face a conundrum; these preparation programs are preparing teacher education candidates for an unknown future. And these future teachers are charged with preparing children for unknown digitally literate futures and career requirements.

What Counts as Literacy?

Certain forms of digital literacy enjoy legitimacy and are both expected and accepted within school environments while other forms are not deemed suitable yet appear more prevalent outside of school (Alverman & Hagood, 2000; Beach, 2012; Black, 2005; Black 2008; Jenkins 1992; Kilinc, Evans & Korkmaz, 2012; Mills & Chandra, 2011, Squire, 2008). In the ultra-traditional model of schooling, typified by nine-month agrarian calendars, separated subjects, and the factory model of attendance wherein the most children appear to have in common and how they are grouped is a birthdate, computer generated assignments, word processed writing, and research via the Internet or web are accepted practice, within limits. Teachers still require children to generate writing on paper, some internet sites are restricted within schools, and certain digital literacy forms of expression are not accepted. Related to the claims of Prensky (2001), the aforementioned researchers recommend that what constitutes literacy and literacy practice broaden to include new and evolving forms of literacy. In essence, traditional literacy practice should expand to include new literacies such as anime blogs, gaming, memes, fan fiction, headcannons, and multimodal forms of expression. Considering how the Internet alone has shifted literacies, emerging literacies must be valued. As literacy shifts at an increasingly rapid rate, these advances must be incorporated into learning environments. Blogs are capable of replacing the traditions of journaling; memes can be accepted ways to respond to events, headcannons can serve as a viable methods of responding to literature, anime and manga can be viewed as appropriate

forms of creative expression, and gaming within classrooms can be suitable practice. As digital literacy evolves, new and yet-to-be created forms and practices of digital literacy will need to be incorporated into schooling, career expectations and the work place.

Digital literacy experts propose that the current generation of teenagers, defined as digital natives of the E-Generation, are more likely to acquire or have acquired the digital competencies needed to effectively traverse multi-dimensional and quickly evolving digital environments. For many adults who grew up in a world of books, magazines, and print literacy, negotiating cyberspace can be uncomfortable. Prensky (2001) claims that individuals who lack digital literacy struggle to live in an unfamiliar world.

Access to Opportunity: The Digital Divide or Digital Literacy as a New Gatekeeper

Access to digital literacy, referred to as the digital divide, has emerged as an issue (DiMaggio & Hargittai; 2001; Flood, Heath & Lapp, 2015; Norris, 2001; Servon, 2008; Warschauer, 2004). In particular, the digital divide threatens to widen existing achievement gaps and further marginalize students who lack access to digital forms of literacy. While access is disparate, especially in urban, rural, and suburban areas, the differences between countries are alarming given rhetoric about global economy and Earth as a global village.

Consider that Coiro, Knobel, Lankshear and Leu report that 99% of US classrooms have access the Internet, the European Union reports 96% Internet access compared to Brazilian schools estimating 26% access and Greece and Poland having 13 to 31% Internet access, while only 5% of Mexican schools were projected to have web access; accessibility rates in sub-Saharan Africa could not be calculated (2008, p. 4). While schools exhibit one view of accessibility, homes and communities can present a differing perspective. Access is tied to economics, whether within or

between geographical areas of a country. Infrastructures are expensive and economics impact access. Despite the promise of global connectivity and immediacy, the issue of access is a gatekeeper to the opportunities afforded by digital literacy.

Coiro, Knobel, Lankshear and Leu recognize the possibilities afforded by digital literacy when they state: "A global network such as the Internet makes it possible to develop and immediately disseminate a new technology of literacy to every person who chooses to access it." (2008, p. 5). However, *choosing* to access and *being able* to access digital literacy is closely tied to economics. In much that same way that older, traditional notions of literacy were tied to having to access books and materials with which to practice, income can impact accessibility to digital literacy opportunities, especially in poor rural and urban schools in the US.

IMPLICATIONS

While digital literacy contains the promise of enhanced learning opportunity, DiMaggio and Hargittai postulate "Internet access is an important resource and inequality in Internet access is a significant public policy issue." (2001, p. 3). As economics emerges as a gatekeeper to digital literacy access, communities and governing structures whether they be schools, school system, families, or countries, will have to grapple with how to provide access to the opportunities digital literacy affords.

Digital literacy has huge implications for teaching, learning, and career opportunities, and these issues correlate to economics. Beach (2012) reiterates that educational practice in the US impacts digital literacy acquisition, calling for a redefined, flexible criteria for assessing student learning that includes myriad forms rather than relying only on criteria created for and linked with traditional print literacies. This implies a teaching force that is current with digital literacies, administration that understands what digital literacy is

and how it functions within school environments, and school systems that invest in digital technologies. Lewis extends Beach's argument, stating that teachers and digital literacy researchers, "need to know what writers of new literacies *do* when they write—what they think about and how they negotiate the demands of new forms and processes of writing." (2007, p. 229).

Economics, access, and education are topics impacted by digital literacy in the US. As traditional literacy, especially print literacy, was once deemed a necessity, Eshet-Alkalai (2004) reminds us that digital literacy skills are becoming basic literacy survival skills for the 21st century. Therefore, educational practices and the use and acceptance of digital literacy skills can also have an impact on work force development.

FUTURE RESEARCH DIRECTIONS

Given that technology and digital literacy will continue to expand, three areas of research should be considered. Research investigating the dissonance between digital natives and digital immigrants, especially in school environments and the workforce should be explored. Research about how children at different ages use digital literacy should be continued. As well, research into why and how some forms of digital literacy enjoy acceptance and legitimacy, particularly in school environs, should be conducted. Finally, access to digital literacy formats, whether it be in schools, in communities, in geographical areas or within the borders of countries should be investigated as well as any restrictions to access that may fall along gender, ethnic/racial, and economic lines.

CONCLUSION

Regarding digital literacy, change is a constant. Shifts in digital literacy within the past 20 years have greatly impacted how people communicate, how teachers teach and children learn in the US and

elsewhere, and the expectations and demands of career and work. Physical space has been removed as a construct and communication and creativity have flourished. Given the rapid evolution of digital literacy, while we do not know how it may evolve, we can know it will evolve, exponentially and in ways not yet imagined.

KEY TERMS AND DEFINITIONS

Anime: Hand drawn Japanese computer animation categorized by colorful graphics, vibrant characters, and fanciful themes.

Blog: Typically an interactive forum or site for discussion or information-sharing created by an individual or group, centered on differing genres such as politics, music, education, health, travel etc., published on the web where entries, referred to as posts allow visitors and members to leave comments about a topic of interest and create a networking community of users.

Cyberspace: Virtual environment where digital communication over computer networks occurs; typical used to represent the many ways ideas, information, and communication are shared via the Internet and networking sites.

Digital Environments: A virtual or cyber-generated environment accessed or created through the use of one or more digital devices such as a computer, tablet, or a cellular phone.

Digital Literacy: A broad term that refers to the use of literacy skills – reading, writing, listening, to communicate and interact within digital environments and/or using devices and cyberspace to compose and comprehend thoughts.

Fan Fiction: Individuals/fans who write new stories using the characters and setting of published, popular media and share via the web.

Headcanons: From the term “canon,” which refers to events and development that happen in the actual published/aired/official text of a book, television show, movie, etc.; it is something that someone wants to believe is true or enjoys speculating on in a particular fandom based on evidence from the canon or other factors, but is generated and actually exists within their own mind.

Internet: The networked system of private, public, business and governmental mainframe, personal, and wireless computer networks utilizing the Internet protocol suite (TCP/IP) to connect devices globally.

Manga: Japanese graphic novels created in Japan and written in Japanese.

Meme: Typically an imitated image such as a photograph that is used to transmit an idea by adding text via the web.

New Literacies: The technical ability and emotional skill level needed to generate thought and to communicate in multiple formats in digital environments.

World Wide Web: A global publicly available hyperlinked information system, accessed through the Internet, also called simply The Web or WWW credited to Berners-Lee (1989).

ICT Investments and Recovery of Troubled Economies

E

Greek Molecular Computing Group, Greece

INTRODUCTION

Over the last few years, many countries faced an unprecedented crisis that negatively shaped their economic and social landscape. Here, the term “crisis” means a general turbulence in economy, which is expressed through various negative events in the public and the private Sector of the economy. Common denominator is the radical increase of unemployment that leads to negative social phenomena, poverty and forced immigration. The discussion that follows is based on (Blanchard & Johnson, 2012).

Indicatively, in Public sector we have reduced GDP (Gross Domestic Product - the total amount of values produced in economy in a year) that is usually translated into potential personnel reductions (or in the best case there are no new hirings). Salaries and pensions are suffering cuts, and the same holds for the budget of public investments (new roads, hospitals, schools, etc.). Additionally, the state faces difficulties in supporting the public debt [the accumulated amount of money that the state has borrowed in the past (loans) from international financial markets in order to support its everyday needs that also include paying back other older loans], constant deficits (the public spending is higher than the collected taxes) and incapability of borrowing new loans from international markets. This happens because of the insolvency of the country based on the fact that the annual debt payments due are not supported from the overall operation of the whole economy and from its fu-

ture development prospects. Accordingly, in the private sector, firms face reduced demand for their products, difficulties in borrowing money from banks, increased tax payments and other negative facts that lead them to reduce personnel, reduce their program of investments and hold money because of the uncertainty prevailing in economy.

The opposite of crisis is development. The term “development” means the expansion of an economy (i.e., new jobs, increasing of salaries and pensions, new public and private investments, new prospects and other positive social and economic events).

One of the most important elements of this brief analysis is the term investment. In simply words, an investment is a dedicated amount of money used to create something, with the hope that this will return in the future some profit (typically a multiply of the initial amount) and will support the economy in its expansion. It is the cornerstone of the prosperity of a society and an economy. Investments are separated in public (roads, schools, energy infrastructure, hospitals, etc.) or private ones (new buildings, new businesses, new production lines, collaboration with public sector, etc.). Development of an open economy can only be achieved through investments. In other words, investments are done so to create wealth. Investments in *information and computer technology* (ICT henceforward) are highly important because they facilitate transactions, reduce bureaucracy and accelerate the operational procedures of state and businesses.

The global financial crisis of 2008 triggered a chain of events that revealed many long term structural problems well established in the foundations of the economy of a series of countries such as Greece, Ireland, and Portugal. Such problems were well hidden for many years and because of the global prosperity their importance was underestimated. Because of this, they could not affect the basic economic figures. Such countries had the ability for years to receive loans from international markets (large investment banks such as Goldman Sachs or JP Morgan) and with this method they could proceed in their everyday operational function. But after the crisis of 2008, the matter of insolvency (the degree to which a country is capable of paying back their loans) turned into a highly significant factor. Based on this, the following chain was triggered:

- The global financial crisis (which was primarily initiated from the collapse of the 4th largest investment bank in the USA, Lehmann Brothers) led to solvency crisis.
- The solvency crisis led to a borrowing crisis (global markets were not willing to borrow some countries because of the doubts they had over their ability to pay back these loans).
- Therefore some countries were not able to receive new loans from financial markets.
- This situation led to a debt crisis, meaning that these countries were not able to receive new loans in order to pay back older ones.
- Eventually, the debt crisis led to public expenditures cuts and an increase of taxes which in turn led to an economical and social crisis.

BACKGROUND

The declination of an economy can be triggered from various factors. Officially it is said that an economy declines (i.e., is getting into recession) if the GDP in two consecutive quarters has a

negative growth. The most significant examples of recession periods over the last century was the American great recession of 1929 - 1933 and the events that took place in the Eurozone after the global financial crisis of 2008. Once the economy declines, a series of negative phenomena are taking place at an economical and social level. All such factors have been shortly mentioned in the previous section. A general reference for studying investments is the (Bodie, Kane, & Marcus, 2013).

In general and indicatively we can mention the following factors that lead an economy to declination:

- **Economic Crisis:** A crisis has not the same form across countries and/or chronological periods. A very good example is the Eurozone debt crisis which was initiated after the global financial crisis of 2008. In Ireland, the crisis was initiated from private banks and then was expanded to the public sector (because government decided to assist private banks with billion of euros to avoid bankruptcy which led to increased deficits). In Greece, the crisis was initiated from the state (the Greek government could not borrow money from international markets) and then expanded to private banks. This was happened because these banks had exposure to the Greek state debt since they had lent the state by purchasing state bonds in the past. There are also other cases that underline this ambiguous approach (e.g., Cyprus and Russia are two such cases).
- **Uncertainty Based on Political Factors:** The most recent example is the situation of Brexit. Investors, firms, individuals and other economic entities are looking for a stable political and economical environment. Major decisions such as the referendum for leaving EU, create uncertainty and instability that can push major firms to change location or individuals to reduce their demand for goods and ser-

vices. Therefore this pushes the economy to decline (meaning recession and therefore reduced incomes and increased unemployment).

- **External or Internal Shocks from Demand or Supply Side:** Sometimes specific technical reasons can create economic instability. Various turbulences from demand or supply side can take place because of major changes in economy. For example changes can occur in consumers' preferences, shortage in raw materials, future expectations from consumers and/or firms, restrictions in exports or imports, capital controls in banks and numerous other reasons. All these, can cause instability which can lead to a crisis.
- **Increased Public Deficits:** In some cases governments spend more in public expenditures (hospitals, schools, pensions/salaries, defense budget, public investments, that is, new roads, ports etc.) than they receive from taxes. They do so based on macroeconomical planning in which they consider the long term benefits are fully covering the short term damage because of the multiplying economic and investment effects in economy. In some cases, they do so simply because their policy makers apply low quality planning which comes along with irresponsibility. If this is the case, the national budget may show public deficits which in turn place additional burdens over the historical debt of the country. This in turn may lead to borrowing problems. This last case, leads to an increase of taxes in the private sector with all the negative effects this may cause. The result is a potential decline of the economy which initially was triggered from public deficits. The Greek crisis is a typical example of this sort of crisis.
- **Reduced Competitiveness:** Innovations in industry, new methodologies, new and complex productive procedures create

intense global competitiveness and a demanding environment for businesses and states. New markets and challenges constantly appear while firms and states that cannot be adjusted in time in this totally new environment see a reduction of their market share in the global arena. If this is the case, the exports are going to decrease while imports will increase (X-M). This triggers instability in the Balance of Trade (BOT) that causes budgetary and macro-economic problems. When this happens, the economy declines and triggers all the negative effects in society. To reverse this development, states and firms must rapidly take decisions and proceed in new visionary plans in order to create new, competitive and efficient market procedures and products that will allow them to strongly stand in global markets.

While an economy can be declined due to various and some times to nonexistent technical reasons (i.e uncertainty), recovery is much more difficult to be realized. It is the same just like saying that a building needs years to be constructed but it is just a matter of seconds to be demolished. Once the declination occurred, meaning that an economy gets into recession for many semesters / years, public policy makers and firms' owners must focus to the recovery which must be realized as soon as possible. The more it holds the greater are the negative results to citizens and to society as a whole and the harder the way is to getting out of the tunnel.

Indicatively, the following fundamental methods can be used for getting an economy back to the root of growth:

1. New private investments, domestic and foreign (FDI - Foreign Direct Investments) in critical sectors of the economy that historically appear competitive advantage in the global market. What is the impact of an investment in economy? Consider the

calm surface of a lake. Consider now a big stone being released above the lake. Once the stone touches the water, homocentric, three-dimensional wavy (outbound) formations are being triggered. Now consider not just one but many stones being released over the lake at the same time. The same multiplying effect holds in the real economy. The more investments are being created the larger the multiplying impact stands for the economy. Many new investments create jobs, wealth and supervalues which leverage the economy initially to moving out of the recession (recovery) and subsequently to further development and prosperity. For example in Greece, the country suffered the most since the global financial crisis of 2008, new investments can be realized in sectors with competitive advantage. This is the case for boutique tourism, renewable sources of energy, shipping, mediterranean foods, services (private education, private health, informatics etc.) and other.

2. Intervention in Fiscal Policy from the ministry of finance. This intervention can come through various forms but the most well known are the following ones: Firstly, with new public investments. This is in line with the so called Keynesian policies. Famous 20th century economist John Maynard Keynes, supported the idea that when an economy comes to declination the state must support the economic circuit by increasing the public expenditures focusing in critical functions of economy i.e building new roads, ports, other important infrastructure so as to accelerate the transactions in the economy and as a consequence to move the economy again. This approach assisted US economy to move out of the recession in 1933. The Hoover Dam (amongst other infrastructure investments) was constructed in this framework. Secondly, by reducing the public consumption in carefully selected public activities which appeared as counterproductive activi-

ties with increased bureaucracy and limited efficiency. This must be executed carefully, by bypassing such activities through the re-routing of the withdrawn resources to other efficient public activities that will actively assist the economy to making reboot. Lastly, interventions in public salaries and pensions where necessary.

3. Intervention in Monetary Policy from the central bank (in EU is the ECB). This intervention basically comes in three forms: Firstly, through the basic interest rate. When the basic interest rate, determined from the central bank, is being lowered, this gives the signal to commercial banks to lower their own borrowing interest rates (which are being added on the basic rate - i.e if for example the basic rate = 1% and the required profit from a bank is 3% then the commercial rate from this bank is $1+3=4\%$) and making the money cheaper. In this way, banks increase the number of provided loans to individuals and firms and thus increase the circulation of money in the economy. This increased circulation can be rooted to investments and to the production of new goods and services. Secondly, by increasing the circulating monetary mass. This is the total number of printed notes and money (cash, deposits, reserves etc) circulating across the economy (in banks, individuals, firms, state and other entities). The Central bank by using some techniques (called open market actions) can increase the monetary mass and thus creating artificial demand in economy over the short time. Inflationary phenomena may be appeared but these can be absorbed at a later time over the mid-long term. Such phenomena are barely appearing when the economy suffers crisis. Lastly, through the combination of the two methods which is the most common in the modern world.
4. Cooperation between the state and private sector in healing the primary reasons that led this economy to decline and designing

the future. This can be realized with interventions in various critical sectors of the economy, in institutions and in the public services that cooperate at everyday basis with the private economy. In general, needs a national general visionary plan that will be executed from both state and leading firms so as to get the problematic economy back on track of development.

ICT INVESTMENTS AND ECONOMIC RECOVERY

For many years the ICT sector was, and of course it is expected to remain, one of the largest employers. In the USA there are many ICT companies that have thousands of employers while it is expected to see an increase in job offers. Naturally, similar elements can be said for other countries. Thus the ICT sector can contribute to an economy by directly creating new jobs.

Every now and then, telecommunication companies introduced new forms of home and business Internet connection. Typically, new connections offer higher speeds and better connections while the price of the new technology is always a bit higher when compared to the current technology. But gradually, the price is getting lower, allowing multiplying positive effects in economy. In order to offer a new technology, communication companies need to invest money so to attract more new customers or to convince existing customers to upgrade to new packages. Thus the new technology does not only offer a better internet home or business connection but increases also the GDP, the incomes and the potential prosperity.

Today all modern states offer some sort of online service for citizens to submit their tax declaration thus avoiding queues and making the whole process easier, faster, and more efficient. More generally, many public services have become available online and some of them through mobile phones. Online bank account access is an example of a service that is both online and

through mobile phones. What is more interesting is that new online or mobile phone services and applications have been appeared. All these are crucial elements that apart from the fact that make the life of citizens easier, allow foreign and domestic investments to be accelerated but also attract new ones. In order to ensure the smooth operation of these new services it is necessary to make investments in new IT infrastructure, hire people, etc., thus contributing to the growth of the economy not mentioning the millions of working hours-saved annually by avoiding bureaucratic procedures and queues. Finally, all these systems will need a regular maintenance framework which allows the further creation of new jobs and new incomes as well.

Impact sourcing is a new “industry” whose purpose is to hire people that will perform digital tasks such as transcribing audio files and editing product databases. It is a typical process of business outsourcing which can boost economic development. Typically, these digital tasks are called microworks and employees complete them by using a web-based interface. This way, skillful people from poor countries can find a job and work for a big company without the need to relocate. We have such examples in India or China. This idea has been introduced by Samasource, a San Francisco based company.

Today almost all companies have a web site where their products and their operations are presented. In many cases, the companies have web stores where customers can directly purchase the company’s products. For example, all publishers have web stores while most companies that produce shoes and/or clothing have web stores too. In addition, most companies have profiles in popular social media sites while they run promotional competitions through their web site or their social media profiles. Naturally, companies need either to have a dedicated ICT department or outsource these tasks to ICT companies that specialize in this area. All these create never thought before business opportunities.

SOLUTIONS AND RECOMMENDATIONS

It is next to impossible to give a specific solution that can be applied to every possible troubled economy. Each economy has its peculiarities and thus is difficult to specialize the general solution. Thus instead of giving a general solution, we will discuss how IT investments can help a specific troubled economy to recover. In our case, the trouble economy will be Greece's economy and the specific solution suited for Greece. The country is facing a debt crisis and has no access to markets for more than seven years. We will not discuss what led Greece in this negative situation. Instead it is better to focus to the future and discuss how the country can possibly get out of this crisis. We have already outlined the benefits of investing to ICT and now will explain how such an investment can improve a troubled economy.

First of all, it is rather important to present a few facts about the use of ICT in Greece. In the end of 2014 65% of Greek households had a broadband connection when the EU average was 76%. Also, on the same year only 9% of companies were selling their goods via web shops while the EU average was 15%. In addition, 84% of enterprises are using e-government services while the EU average is 88%. These figures clearly show that there is plenty room for improvement. In addition to these characteristics, there are some serious drawbacks in the current situation. First, it seems that computer literacy is high enough, nevertheless, it is not that complete (e.g., most people know next to nothing about computer hardware and internet connectivity). Also, ICT systems are poorly maintained. Moreover, there is no plan for the use of public information and data. But the most crucial problem is that in every change of ministers and/or government a new political plan is adopted. From a purely technical point of view, there was no central planning on what computer platforms to use so that different ministries use different systems and platforms. Obviously, a good solution to avoid this sort of chaos is to

adopt a specific open source computer platform and switch all existing systems to this platform. Apart from this obvious move, one can propose the following interventions as well:

- The modernization of public administration (e.g., reduction of bureaucracy by adopting a paperless office).
- Reconnection of citizens with the state (e.g., e-unification of public services and systems).
- Adoption of a new digital personal card for all citizens that will provide them full access to all public services.
- Open access to public data.
- Adoption of cloud, etc.

These points could create new jobs, facilitate transactions, save working hours and make the various public facilities more attractive to use by citizens and firms. They will also attract new foreign investments that will boost the economy with all the positive multiplying economic effects that this may cause. In addition, it is mandatory that the government should urge enterprises to enter the e-market and people to prefer e-shopping (a side-effect of it would be a reduction of tax evasion). Also, the government should strive to have skillful citizens, which naturally means that school curricula must be adapted accordingly.

FUTURE RESEARCH DIRECTIONS

We have explained what a troubled economy is and how ICT investments can help such an economy to stand on its own two feet. Since there are no general recipes on what exactly should be done in every possible case, it would quite interesting to try to devise some method (or "algorithm") that could guide someone to choose the best solution for each particular case. Naturally, such a method should take into consideration a number of factors such as the level of training of citizens, the current technological infrastructure and achievements

(i.e., one should propose solutions that make sense), the potential availability of loans that can be rooted to ICT projects, the general legal framework, the level of international collaborations from firms and state, the general investment and tax environment that can attract ICT global firms to move resources in this country etc.

CONCLUSION

Economic recovery is not something that can be achieved overnight. The government of a troubled economy or the administration of an international organization that assists troubled economies to recover (i.e IMF, EU etc), needs to carefully plan the possible recovery of the economy. Clearly, an economy can recover when many medium and large scale investments are being made at a constant rate in sectors with competitive advantage. However, it seems that amongst others, ICT investments are quite viable mainly because they are not so demanding in terms of funding. For example, in order to build a shipyard it is necessary to find a good location, build the appropriate facilities, and install the required equipment. However, in the case of ICT investments, one needs a room, a few computers and some trained personnel. This core infrastructure can massively assist entire organizations and public services accelerating transactions and creating room for multiplying positive economic phenomena. Thus when a nation invests in ICT, actually invests in the future and one can expect only growth of the economic output and prosperity for its citizens.

KEY TERMS AND DEFINITIONS

Economic Crisis: A situation in which the economy of a country experiences a sudden downturn brought on by a financial crisis.

Economic Recovery: A period of increasing business activity signaling the end of a recession.

Economy: The large set of inter-related production and consumption activities that aid in determining how scarce resources are allocated.

ICT: An umbrella term that includes any communication device or application, computer and network hardware and software, satellite systems and so on.

Investment: An asset that is purchased with the hope that it will generate income or appreciate in the future.

Uberization (or Uberification) of the Economy

E

Nabyla Daidj

Telecom Ecole de Management, France

INTRODUCTION

The management of technological innovation is one of the most demanding challenges today (Dodgson et al., 2008). The external environment characterized by globalization, convergence, competitive/market uncertainty, time-to-market pressure, shortening product lifecycles is also based on knowledge, information, fast-changing technology and an innovative economy. In recent years a series of innovations and trends have changed the way people perceive technology. The global availability of the Internet, along with innovations (products, services and applications) explain certain aspects of the dynamics of the innovation process, the diffusion of technology and the development of various platforms (product and service marketplace, social networking platform, content platform).

The Uber taxi-booking smartphone app, matching those who have cars with people who need rides quickly, was created in 2009 in the US and has been progressively launched all around the world. Since this pioneering app, several other start-ups operating in various activities (transportation, flower and food delivery, events, home services, legal services) have adopted a Uber-like business model (BM) and more and more companies are looking to disrupt regulated industries, such as banking or healthcare.

Uber has been a driving force behind the emergence of a new kind of platform connecting consumers and providers in real time and organizing information without any ownership of the products concerned. Uber, based on trust (MacDonald, 2016), has changed the rules of the

economic game and its success has inspired the term “uberization”.

The objective of this chapter is to gain a more precise understanding of uberization and in particular its theoretical scope. How would we combine uberization with other accepted and widely used concepts in economics and strategy, such as platforms, multi-sided markets, externalities and business ecosystems? Is uberization a relevant concept, an all-purpose word with a multitude of meanings or just a buzz word?

This chapter attempts to answer these questions and is structured as follows. This first section introduces the topic and key concepts and presents a brief overview of the evolution of the Uber phenomenon to a larger trend named uberization or uberification. The second section discusses the conceptual and theoretical framework to analyze the development of uberization. It develops a strategic and economic perspective. In section 3, several recommendations are proposed. Section 4 suggests directions for further research. Section 5 concludes.

BACKGROUND

From Uber to Uberization

Uber (the mobile application) is not uberization (Table 1). In recent years, a number of studies have been performed to gain further insight into the uberization phenomenon, notably empirical publications. The particular attention given to uberization (even in non-specialized press) shows how its importance has grown year by year since

Table 1. From Uber to uberization

Uberization of Work - Employment	“But of all the ways that Uber could change the world, the most far-reaching may be found closest at hand: your office. Uber, and more broadly the app-driven labor market it represents, is at the center of what could be a sea change in work, and in how people think about their jobs”. (Manjoo, 2015) “There has been a lot of debate about how online platforms have changed the nature of work. In some cases, on-demand companies have been harshly criticized for making employer like demands on workers but denying them basic benefits and protections”. (Bernard, 2016)
Uberization of Finance and Banking	“We are on the verge of the Uberization of finance, which will bring multiple new opportunities but also a range of new risks (...). Uber is a high-tech middleman that is making the intermediaries of the past obsolete. The financial world is one of the most mediated industries on the planet, and that is precisely what is about to change. (Karabell, 2015).
Uberization of Business Schools	“What could more surely come next is the appearance of low cost and/or no frills business schools, focusing on the essentials and offering options. That’s partially the idea of online business schools, with some success, but it never really diffused to brick-and-mortar or hybrid models. With the strong discussions on fees in many countries of the world, there is now room for the emergence of a new type of business schools.” (Therin, 2015).

Source: specialised web sites.

the end of the 2000s. The definitions given in the general and specialized press are generally broad or applied to a particular industry or activity.

Uberization should lead to a transformation of the entire economy. Uberization is a phenomenon based on on-demand services (enabled by the Internet and smartphones) and peer-to-peer platforms combining imitable features such as dynamic pricing sometimes called “surge” pricing (Horpedahl, 2015; Smith, 2016), mobile payment, rating systems, algorithmic and data management (Hall et al., 2015).

Towards a New Kind of Capitalism or Its End?

Uberization may turn out to be a concept in the future seen as a new, complex and dynamic form of liberalization (economy) and a more perfect supply and demand equilibrium (market).

Some authors suggest the evolution of capitalism towards ‘postcapitalism’ (Mason, 2015) or ‘platform capitalism’ based on a physical and digital transformation of how goods and services are produced, shared and delivered and how customers (final consumers) engage directly with each other through on-demand platforms (Davis, 2016); others consider uberization “as a form of populism” (Kyrou, 2015, p. 106).

Some experts are even predicting the end of capitalism with the development of sharing, collaborative and participatory practices. However, the rules governing these practices activities (Cusumano, 2015) should be compatible with the market economy and capitalist system. Experts already believe that the potential for growth of the sharing and on-demand economy will be significant in the future. This nascent economy will set the stage for reshaping the economic system, renewal of the market relationships between economic actors, changes in the nature and structure of work (labor considered as a commodity) and work organization and consumer behavior shifts.

The uberization phenomenon calls for a multidimensional framework for understanding its development and impact including the following levels of analysis.

Country Level

The impact of uberization may differ in complexity from country to country depending on the national legislation concerned. The questions raised by uberization have become more pressing as they are closely related to a wide variety of laws and regulations including labor law, antitrust and competition law, and corporate law. The uberization of the economy is widely debated

all around the world and reactions differ from one country to another. In the European Union, UberPop (where the Uber service is directly challenging the taxi market), has given rise to many disputes. Consequently, “a number of regulators in Member States took actions based on existing legal frameworks that resulted in administrative and/or criminal charges against Uber drivers and management (e.g. Netherlands, Portugal, France, Spain and Germany). As a response, Uber submitted complaints to the European Commission” (Azevedo & Maciejewski, 2015, p. 1). In India, the situation is quite different where it was not so much the regulatory and legislative framework that posed problems, rather the Uber mode of payment. Finally, Uber has accepted cash payments for rides. In the United States, Uber claims “that it is preempted from all regulation because it is an information service provider under the Telecommunications Act of 1996.” (Elliott, 2016, p. 743).

Industry and Market Level

There are several factors that determine the market structure of a particular industry: buyers and sellers (number, interactions between them, bargaining power), prices, production and selling processes, and product/service differentiation based on innovation. Uberization affects all sectors of the economy, encourages the emergence of new players, creates new market opportunities and changes the competitive environment and the degree of competition to a certain extent. But as mentioned by Gabel (2016), “entry into the taxi industry involves few risks. Entrants have lower costs than the incumbents, sunk costs are small, and modern technology makes it easy to hail a cab using the Internet. Despite large scale entry and low barriers to entry, monopoly power persists. The persistence of monopoly power illustrates that new technologies may not quickly eviscerate monopoly power.” (p. 527).

Company Level

“Traditional companies now have another set of competitors to worry about – Internet startups in the “sharing economy.” These new companies are actually Web platforms that bring together individuals who have underutilized assets with people who would like to rent those assets short-term” (Cusumano, 2015, p.32). Consequently, uberization may lead most of the incumbent large companies, more often than in the past, to review their future strategy in order to adapt to the arrival of several new players and to achieve a sustainable competitive advantage based mainly on differentiation. There is a risk today that temporary (or transient) advantage is becoming the rule rather than the exception (McGrath, 2013; Carpenter et al., 2014; Daidj & Aras, 2015).

Platform Level

Uber can be considered as an ICT platform and uberization refers then to a platform-based economy reshaping firms’ and sectors’ boundaries. In recent years, the phenomenon of the platform has been observed and the concept of the platform has been thoroughly examined by several scholars (see next section) who mostly focus on specific theoretical aspects of this issue or investigate particular industries.

UBERIZATION: A REVIEW OF LITERATURE

Theoretical studies on uberization are still limited even if scholars have recognized the importance of the phenomenon which could be analyzed through the lens of marketing, strategy, finance, international business, human resources management, information systems and labor law. Uberization is a complex, dynamic and multi-dimensional issue. Probably due to the many disciplines involved in uberization – spanning a diverse field from orga-

nization and management research to computer science and information systems – a unified body of research on uberization and the resulting social, economic and strategic implications remains a matter of debate.

Various points of view of different scholars in two main disciplines are presented below as interaction and interdependence between economics and strategic management have become frequent and multi-faceted. The economics literature has addressed more specifically the challenging platform issue by defining several types of platform (one-sided, two-sided and multiple sided markets) and through the concept of externalities. In the strategy literature, uberization typically revolves around innovation, firms' strategies, business models, business ecosystems and relationships between actors shaping the emergence and the development of different types of cooperation and competition (i.e. coopetitive practices). This section is dedicated to emerging issues with regards uberization of the economy.

Uber: Innovation and Economic Impact on Business Models

Christensen in his book, "The Innovator's Dilemma" (1997) split new technology into two categories: sustaining and disruptive. Sustaining technology relies on incremental improvements to an already established technology. Disruptive technology is a term used for the first time to describe a new technology that unexpectedly overturns the dominant technology in the market sector and that forces changes in industry frontiers, business processes and business models (BMs). Disruption is rarely the result of a single innovation but occurs when two or more technologies converge.

But innovation is not necessarily technological. According to the Oslo manual (OECD, 2005), an innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations. "If

anything, "uberizing" probably means "trapping" a set of innovative procedures – geo-location, online payments and workforce management and distribution – into an "app-accessible service" or a "sweatshop", according to its critics, with lower entry barriers since people monetize resources they already own." (Aloisi, 2015, p. 10).

Regarding BMs, they evolve as the technology matures. "Disrupters often build business models that are very different from those of incumbents" (Christensen et al., 2015, 49). But can Uber be considered as a disruptive innovation and/or a disruptive business model? Nevertheless the following question remains unanswered today. According to Christensen et al., (2015), "Uber is clearly transforming the taxi business in the United States. But is it *disrupting* the taxi business? According to the theory, the answer is no. Uber's financial and strategic achievements do not qualify the company as genuinely disruptive—although the company is almost always described that way" (p. 47).

Uberization, Platforms, and Multi-Sided Markets

Since the beginning of the 2000s, the platform issue has been studied from an economic point of view by several scholars (Caillaud & Jullien, 2001; Armstrong, 2002; Evans, 2003; Ferrando et al, 2003; Rochet & Tirole, 2006; Armstrong, 2006; Cortade, 2006; Evans & Schmalensee, 2010; Weyl, 2010). Platforms are based on technologies that provide support for, and interact with, products and services of other firms. Gawer and Cusumano have highlighted the critical role played by platforms (Gawer & Cusumano, 2002; Gawer & Cusumano, 2008; Baldwin & Clark, 2000).

More recently, Staykova and Damsgaard (2014) considered that one-sided, two-sided and multi-sided platforms should be distinguished clearly (Table 2). "[...] one-sided platforms differ from one-sided markets which function predominantly as resellers (Hagiu and Wright, 2011). One-sided platforms facilitate the communication between

Table 2. From one-sided to multi-sided platforms

One-Sided Platform	Two-Sided Platform	Multi-Sided Platform
• Danske Bank (with Mobilpay) Barclays (Pingit) • Betfair (the world's biggest betting exchange) previous activity before allowing other bookies to offer bets in competition with one another.	• The game console sector (consoles, video games) • Credit cards • Yellow pages	• Exchange platforms (peer-to-peer platforms): Airbnb, Uber • Product marketplace: Amazon, ebay • Payments platforms: Paypal • Social networks platforms: Facebook

Source: Elaborated by the author.

the users of the platform who form one distinctive group of consumers which exhibit same-side network effects and have interchangeable roles. Thus, they differ from the two-sided platforms which link two distinctive groups of users (consumers and merchants) with strong cross-side network externalities” (see below).

Multi-sided platforms allow direct interactions between two or more distinct sides and each side is affiliated with the platform. Affiliation refers to the fact that users on each side have to make platform-specific investments that are necessary in order for them to be able to directly interact with each other. The investment could be “a fixed access fee, expenditure of resources or an opportunity cost” (Hagiu & Wright, 2015, p. 6). According to Hagiu and Wright (2015), Uber can be considered as a multi-sided platform (MSP) enabling independent contractors or professionals to deal directly with clients. MSPs reduce transaction, coordination and search costs between two or more distinct groups of users (Staykova & Damsgaard, 2015).

Staykova and Damsgaard's (2014) approach is also of interest because it allows a better understanding of platform evolution as it introduces changes in the platform and development dynamic within each stage as the competition conditions evolve based on evolutionary economic concepts.. A platform is defined “as one-sided since the new product or service is still developing. As the platform becomes two-sided during the next stage, the level of competition slowly rises, but the preference is given to cooperation. The competition intensifies as the platform matures and becomes multi-sided.” (Staykova & Damsgaard, 2014, p. 12).

Uberization, Network Externalities, and Externalities

The platform industry is generally characterized by the existence of high network externalities. Network analysis is often related to the theory of positive network effects which describes a positive correlation between the number of users of a network for a specific good/service and the utility of this good/service. “There are many products for which the utility that a user derives from consumption of the good increases with the number of other agents consuming the good” (Katz & Shapiro, 1985, p. 424). Network externalities are a well-known phenomenon in the IT sector, though they exist elsewhere (Arthur, 1989; David, 1986; Foray, 1989, 2002).

Two types of network externalities can also be distinguished: direct and indirect externalities. Direct externalities appear when the satisfaction (utility) stemming from the consumption of a product or use of a service directly derives from the number of individuals already consuming the product or using the service. It is thus an intra-group externality. The more the product is used, the more value it acquires in relation to others. Indirect externalities emerge when the demand for a product in a market depends on the offer of another product without which the first cannot function. The appearance of this type of externality is conditioned by the existence of two complementary products forming a ‘system’ product or a platform (Daidj & Isckia, 2009). In this context, two categories of agents are distinguished, and the value of a product for one category is positively

correlated to the number of agents on the other side of the market. This is an inter-group externality. The platform thus internalizes the indirect externalities which can usually be divided into two types: membership (or affiliation) externalities and usage externalities (Rochet & Tirole, 2004). Uber success can be explained partly by its capability to benefit from network externalities, mainly in recruiting drivers. Its development strategy has aimed to reach this critical size both at local and international level.

Uberization is also closely related to scalability (taking advantage of network effects) and to a specific kind of externalities, named reputation externalities. Reputation mechanisms could reduce inefficiencies in markets with asymmetric information and assure quality of service. Even if reputation effects can be extended beyond market platforms (Noskoy & Tadelisz, 2015), reputational externalities represent a key to the success of a peer-to-peer market place based on experiences made by individuals. Reputational risks should not be underestimated; a good reputation is crucial leading to the setting up of reputational feedback mechanisms and ratings.

At a more general level, economists make a distinction between what are called positive and negative externalities. Externalities represent a major cause of market failure. Rahel (2016) has analyzed the economic impact of Uber on the taxi industry and the potential negative externalities (efficiency, quality, and safety) that come with this new technology.

Uberization and Business Ecosystems

The 2000s have been characterized by the emergence of a “new form” of network organization: the business ecosystem (BE). This type of network spans a variety of industries and it is often associated with platforms. Moore (1996) defines the business ecosystem as a business community that brings together various inter-dependent players who belong to different sectors. BE refers to an

undefined, non-geographic network (often based on a platform” or “on platforms”) characterised by cooperative and “open” practices (among suppliers, organizations and customers) in order to co-create value (Daidj, 2013; Daidj, 2015).

Electronic platforms play a strategic role in enhancing value creation within the business ecosystem by sustaining input from various stakeholders. Even if the platform needs a leader, firms are embedded within business ecosystems, the performance of which influences the success and survival of all their member firms. Uber, through the Uber app, has been considered as an independent transportation provider creating a new kind of business ecosystem including, in particular, independent third party transportation partners (driver partners). Smith (2016) has used the expression of “uber-all ecosystem” (p. 389).

More generally, the uberization of the economy has led to the development of intermediaries within each sector and to new partnerships between main players.

SOLUTIONS AND RECOMMENDATIONS

Companies are moving forward with digital transformation at varying paces and experiencing varying levels of success. Since its creation, Uber has radically disrupted an entire industry (transportation) and has continued to transform many industries around the world, removing economic, social and behavioral barriers. All stakeholders are affected by Uber’s development: regulators, incumbents, services providers, employees (for some professions), consumers etc. All of them will have to face several challenges. Challenges are competitive, technological and organizational.

As the previous sections have shown, multi-sided platforms and resulting peer-to-peer platforms, such as Uber, are complex phenomena and corresponding research is very diverse. Accordingly, several theoretical perspectives can be applied to investigate the related phenomena.

FUTURE RESEARCH DIRECTIONS

Uberization is an evolving concept and researchers should be aware that uberization issues are strongly interconnected and that multi-disciplinary approaches will be required to address them in a comprehensive manner. Uberization is at a very early stage and will impose market and technological developments and will require changes to work patterns. Further work is required to better understand the impact of uberization on performances within business ecosystems, including case studies with different types of impact assessments. Further research into the relationships between the main actors will expand the base of evidence to reflect changes that have occurred in recent years in the business landscape in a context of uberization.

CONCLUSION

This chapter has highlighted the main challenges related to uberization. This fast-growing phenomenon is seen today as an important feature of economic transformation. Uberization exposes both traditional groups to direct competition with new entrants (especially peer-to-peer platform operators). The regulation by the public authorities based on the principle of equal conditions of competition for all operators on the market does not want to give new entrants a free rein. Uberization also raises questions about a radical reform of capitalism and of the market economy. Much of the interest in the uberization economy focuses on these online platforms that put forward the virtues of the sharing economy. But facilitating exchanges (of resources and/or competencies) on a platform (such as Uber) does not mean that the human being is put at the center of the economic and social development. Herein lies the heart of the problem.

KEY TERMS AND DEFINITIONS

Business Ecosystem: Interorganizational network (coalition) which brings together actively involved organizations who belong to different sectors, but share the same interests, values and common goals.

Disruptive Technology: Disruptive technology or innovation create major changes in industry frontiers, business processes and business models.

Network Effects: They are related to correlation between the number of users of a network for a specific good/service and the utility of this good/service.

On-Demand Economy: Refers more and more to uberization closely related also to sharing practices spreading across several sectors as banks, insurance, tourism, transport, food delivery, connected health or retail.

Online Platform (Company): Integrated web-based platform company allowing people (consumers, “independent contractors”) who want to share assets online.

Peer-to-Peer Platform: Platform whereby two individuals can communicate, interact (and sell) directly with each other, without intermediation by a third-party.

Sharing Economy: known also as collaborative consumption referring to peer-to-peer-based sharing of access to goods and services.

Uber: The name of a technology company who has launched a smartphone-based app allowing car-sharing service (connecting ride-seekers and UberX drivers). Uber's development has inspired the term 'uberization'.

Adaptive Hypermedia in Education

E**Vehbi Turel***The University of Bingol, Turkey*

INTRODUCTION

Since the definitions of the pertinent terms such as multimedia, multiple media, interactive multimedia and hypermedia are given in a previous study (Turel, 2015a, pp. 2495-96), in this article, only the definition of adaptive hypermedia (AH) is focussed on, and the role of adaptive hypermedia (AH) in education is concentrated on. The aim of this article is: (a) to give the definition of AH and state what AH means, and (b) to explore the role of AH in education at this digital age, in which the majority of learners are generally digitally fluent and competitive (Turel 2015b, Gros et al., 2012, pp. 190-210) although some claims otherwise (Bullen, Morgan & Qayyum, 2011, pp. 1-24). Pedagogically and epistemologically, educational institutions (i.e. nursery, primary, secondary and high schools, colleges, vocational schools and colleges, life-long learning centres, adult education centres, and universities) should respond to such learning demands and differences to accommodate the digital-literate, wise and efficient learning style preferences of today's learners by providing AH learning materials for them. More frankly, educational institutions have to use and provide AH learning materials for their learners in order to be competitive in this digital age (Turel, 2014a; Turel, 2013; Duncan-Howell, 2012).

BACKGROUND

When educational (computer) technologists speak of adaptive hypermedia (AH), mostly one thing comes to mind. It is the use, combination and delivery of digital video, audio/sound, text,

visuals (i.e. pictures/images/photographs, graphics, tables, figures), animations, hyperlinks, optimum combinations, instructions etc. on the same digital platform, which are totally computerised and under computer as well as learners' control. This digital platform also enables learners / users to make preferences, record these preferences, their individual needs and learning goals, and then uses them throughout interaction with the learners in order to meet their personal needs so that they can learn better (Turel, 2015a, p. 2497; Turel 2015b). In other words, AH (a) is a digital environment where a wide range of digital elements are combined and delivered on the same environment through hyperlinks (Figures 1 and 2), (b) has a learner model where learners can make preferences, record these preferences, their individual needs and their learning goals, and (c) uses the learner model to adapt the contents of the hypermedia according to the learners' needs (based on the data provided and the preferences made by the learners through the learner model) (Brusilovsky 2012, p. 46; Brusilovsky, 2007, Brusilovsky & Millán, 2007; Brusilovsky, Eklund & Schwarz, 1998). It is because of this 'adaptation feature' that it is now called 'adaptive hypermedia' (AH). AH is relatively a new direction in the field of educational technology (Brusilovsky 2012, p. 46), consists of different models (Kahraman et al. 2013, p. 60) and can be classified according to its application areas such as Educational Adaptive Hypermedia, which is the most popular area for research (Brusilovsky, 1996). To sum up, when the combination and delivery of a wide range of digital elements on the same digital platform offers 'personalised learning', then such a digital platform is called AH.

Turel, 2015b, p. XXXIII.*

*Figure 2. An example of hypermedia as well as hyperlinks. The “word in red colour” (i.e. abide by) contains a hyperlink. When it is clicked on, the provided definition is displayed for the learners
Turel, 2015b, p. XXXVIII.*

ADAPTIVE HYPERMEDIA IN EDUCATION

In terms of education, outstanding differences between AH and conventional materials (CMs) exist. These are: (a) the combination and instantaneous delivery of different digital elements on the same digital platform, (b) being navigational and interactive, (c) user control and ease of use

and (d) offering ‘personalised learning’. The objective of educational AH is to design and create pedagogically sound and epistemologically flexible learning environments which (a) not only supports a wide range of learners who are diverse in terms of abilities, disabilities, levels, interests, backgrounds, and other characteristics, but also (b) enables learners to make maximum use of the available personalised interactive and

simultaneous learning material (Shute & Zapata-Rivera, 2012; Brusilovsky, 1996), which is also cost-effective. We can now look at these as well as the other aspects of educational AH.

Adaptive Hypermedia Has More Features

AH has a wide range of combined flexible elements and features. These can make (a) input comprehensible, (b) learning enjoyable (Soboleva & Tronenko 2002, p. 493; Trinder, 2002, p. 75) and (c) adapt the same learning material to the needs of a wide range of diverse learners (Shute & Zapata-Rivera, 2012; Brusilovsky, 1996). All of these can, as a whole, result in better learning (K Govindasamy, 2013; Stepp-Greany 2002, p. 172). On the other hand, CMs (i.e. traditional books, off-air materials, tape cassettes and videotapes) do not have many such elements. For example, traditional books only feature texts, pictures/graphics/figures, indexes and inter-textual citations although 'Choose Your Own Adventures books' series (e.g. *The Cave of Time*, *House of Danger*) are also explicitly designed as 'hyper-textual'. In the same way, off-air radio-programs and tape cassettes feature 'audio-only', while off-air TV programmes and videotapes feature both sound and visuals. Those created for learning/teaching purposes such as tape cassettes and videotapes are sometimes accompanied with learner's books. Similarly, traditional hypermedia (i.e. multimedia, interactive multimedia) has its own limitations. For example, traditional hypermedia provides all learners with the same contents and hyperlinks regardless of their wide range of profiles, needs and individual differences.

Not only is learning a multi-channel phenomenon, but also learning-style preferences are a wide range of - which can be described as learners' natural, habitual and preferred (i.e. biological, developmental and conscious or subconscious) ways of processing, acquiring and representing (new) knowledge and skills -. While CMs provide a limited learning environment, AH provides a

multidimensional, multi-sensory and interactive environment in which not only input can be presented in different ways (Herron et al., 2002, p. 37; Leffa, 1992, p. 66), but also input can be adapted to the learners' individual characteristics and needs. Not only can this meet the needs of learners who are diverse in terms of abilities, disabilities, levels, interests, backgrounds, and other characteristics, but this can also meet the needs of different individual learners who have different learning-style preferences such as auditory, visual, tactile, kinaesthetic, group and individual (Carson & Longhini, 2002, p. 408). For instance, while the provision of audio-only meets the needs of auditory-learners, video and (supplementary) visuals can meet the needs of visual-learners (Turel, 2014b; McLoughlin, 1999, pp. 222, 229). Equally, typing a word or sentence, clicking on a choice, recording their own voice, or dragging and dropping a word, sentence or picture meets the needs of tactile- and kinaesthetic- learners.

AH features the combination of diverse elements which provides interactivity. This facilitates the negotiation of meaning, and it is necessary in learning (Harrington & Levy, 2001, p. 15; Hegelheimer & Chapelle, 2000, p. 42), as learners can access hyperlinks, glossaries, feedback, subtitles, answers, and optimum flexible, customised and conditional combinations (Turel, 2015a; Turel, 2012, pp. 40-41) immediately, and find out what and why they have not understood, and the underlying assumptions.

All of these efficient features of AH facilitate learning; draw learners' attention to their weaknesses and certain aspects of input and can result in depth processing, which are necessary conditions for learning. For example, the combination of different elements can make input comprehensible. This is a requirement of the comprehension input hypothesis and theory, which state that learners acquire only when they understand, and therefore "consider intake synonymous with comprehensible input" (Krashen; 1984; p. 21; Tschirner, 2001, p. 311). It is also a requirement of the social learning theory, which "posits that

people's judgements about their potential ability to perform well or to cope in a situation actually affect their efforts..." (Robinson, 1991, p. 157). The person perception theory, which requires us to avoid focussing learners' attention on their weaknesses so that they do not develop negative judgements about their ability to perform (ibid: 157), and the social-psychological theory and the socio-educational model, which focus on the role of attitudes and motivation in learning (Masgoret & Gardner, 2003, pp. 124, 127, 158-9; Gardner, 1985, p. 158) also require us to provide comprehensible input for learners. Comprehensible input can also be considered as a requirement of the cognitive load theory and working memory, as incomprehensible input can cause risk of overload on limited working memory (Kalyuga, 2000, p. 161; Sweller, 1999).

The combination of optimum different elements on the same digital environment in AH can draw learners' attention to certain salient input. This is a requirement of the noticing hypothesis and the attention theory, which suggest that paying/drawing attention to (specific) forms in the input is necessary for learning (Nicholas, Lightbown & Spada, 2001, p. 721; Williams, 2001, p. 335). This can be implemented more effectively especially in AH environments, as the contents can be adapted to the needs of different individuals who are diverse.

The combination of optimum different elements on the same digital platform in AH is also the requirement of the dual-coding theory and the generative theory of multimedia, as it provides learners with more than one concurrent mode/element which targets to teach one thing. It is learned better than those coded only in one mode because dual-code provides more paths of recall, which can aid to build two types of recall cues in memory (Ginther, 2002, pp. 133-67; Moreno & Mayer, 2002) although this might not always be the case with all combinations (Amrhein et al., 2002, pp. 843-57; Kalyuga, 2000, pp. 162-63), as it also requires considering the requirements of the cognitive load theory and working memory.

All Elements Are on the Same Platform

While working with CMs requires learners to use additional sources (i.e. accompanying auxiliary books, answer keys, dictionaries, grammar books etc.), which might be frustrating, distracting and time-consuming for learners (Leffa 1992, pp. 70-72), in AH, all elements are on the same digital platform and learners find such a combination and delivery motivating (Soboleva & Tronenko, 2002, p. 483; Ayres, 2002, pp. 247-48). As a result, AH provides considerably greater opportunities for ease of use and learner-control than have been possible with CMs. For example, Leffa's (1992, p. 71) study revealed that "the electronic glossary... was not only more efficient but also seemed to demand no previous training..." and "...was significantly superior to the traditional dictionary"; as less time needed for the electronic mode (ibid, p. 72) and it resulted in better comprehension (ibid, p. 70). Likewise, AH is more efficient as well as more cost-effective in comparison to traditional hypermedia, as the former adapts the learning contents to the needs of different learners who are diverse in terms of abilities, disabilities, levels, interests, backgrounds, and other characteristics.

Learners can instantly access different parts of AH (i.e. video, audio, optimum combinations, feedback, glossaries, available sections, syntax, lexis, subtitles etc.), which are combined and delivered on the same digital platform, all of which are good opportunities to exercise control over input (Tschimer, 2001, pp. 312-3) unlike with CMs.

These positive aspects of AH can enable learners (a) to find out the difficulties, the right solutions, what the rules are; (b) to analyse the mistakes that have been made; and (c) to find out why they have made such mistakes by assessing their answers, recording and scoring them, pointing out and explaining mistakes (Mangiafico, 1996, p. 52). This capability provides more real-world learning contexts and more authentic and interactive tasks. Ashward (1996, p. 80) states that "the ability to display such a variety of resources,

to link them together, and to combine all these resources with tutorial programs on the computer provide a highly sophisticated, yet potentially easy-to-use and easy-to-author medium for developing education materials in any subject". Equally, these positive aspects are highlighted by Fox (1995, p. 43), and learners also appreciate them (Brett, 1997, pp. 46-7).

Adaptive Hypermedia Gives Learners Control

AH provides learners with the opportunity to learn any subject at their own pace, without fear of making mistakes in the presence of a teacher or other learners. It is a tension free environment in which learners can use AH environments individually, as no teachers and friends are present. Especially, during self-study, AH is a private and flexible workplace where learners can take risks; work in their own place (Tschirner, 2001, p. 307), in their own time, at the pace they need, and in the way they enjoy; as it gives them the control (Soboleva & Tronenko 2002, p. 493; Trinder, 2002, p. 75) and provides them with different choices, tasks and feedback. Moreover, the contents of AH are adapted to the needs of individual learners. All these positive aspects can make them feel more comfortable and might result in promoting development of self-confidence and provoking working hard. It is due to these reasons that learners do not complain about the fear of making mistakes. Conversely, they express their comfort of working with hypermedia. Ease of use - in relation to pacing and control- (Trinder, 2002, p. 75; Brett, 1997, pp. 46-7) and "user-friendliness" - at an operational level - (Fleta et al., 1999, p. 55) are some hypermedia features found most useful. User-control is a feature that has an impact on learning effectiveness (Peter, 1994, pp. 157-8), which is also considered an essential principle in instructional design (Hoven, 1999, p. 91) and a condition that is necessary in autonomous materials (Watts, 1997, p. 7). It is also a requirement of autonomous learning and development, the main

way of life-long learning, and the requirement of the autonomous learning theory, which "demands that learners take control of their learning" (Voller, 1997, p. 106).

Adaptive Hypermedia Motivates Learners

As AH offers learners many elements on the same digital environment, it is highly motivating. When learners make mistakes, this does not even demotivate them because they have the opportunity to receive instant and meaningful feedback, and practise as many times as they want and need to. Learners find hypermedia motivating and they are engaged, active, attentive and interested in hypermedia when they work with it (Soboleva & Tronenko, 2002, p. 483; Lyall & McNamara, 2000, p. 135). This is an important factor in learning especially during autonomous study because "how to engage the interest of the learner and so sustain his motivation to learn" is considered "a related problem for the writer of self-study materials" (Frankel, 1987, p. 53).

Most importantly, (1) motivation is "directly linked to achievement" according to the socio-educational model' (Masgoret & Gardner, 2003, p. 129), which suggests that integrativeness and attitudes towards the learning situation cause learners' motivation to learn input and motivation is responsible for achievement (ibid: 24; Gardner, 1985, p. 158). (2) Motivation is also common to all models of learning (i.e. the acculturation model, the conscious reinforcement model, the intergroup model, the interactionist model, the LMR-plus Model, the monitor model, the social context model, the social psychological model, the elaboration theory model, ibid: 25-66).

Adaptive Hypermedia Prepares, Directs, and Guides Learners

Since AH (a) enables the combination and delivery of different elements on the same digital platform more effectively (Turel & Kılıc, 2014; Turel 2012,

pp. 35, 45) such as supplying a non-linear editing facility (Tschirner, 2001, p. 307) and (b) also adapts the contents to the needs of individual learners, it enables materials writers to create effective and interactive applications directly to their customers' specifications, their needs, interests and learning styles (Cauldwell, 1996, p. 526). AH can prepare learners more effectively and adequately for input, as it empowers materials writers (1) to provide learners with different elements such as unknown items, technical words and concepts (i.e. terminology), the objective of the topic, syntax, special features of text type/input, short audio messages, short video clips, sample sentences, graphics, animations, visuals, simplified written versions of the text; short information about the topics, the speakers of the existing audio and video clips, their roles, how they interact, the content and cultural differences (Turel, 2014c). (2) Since featuring, delivering and combining different elements on the same digital platform, AH can guide learners more effectively. For example, when learners make a mistake, they receive adapted instant and meaningful feedback. This can enable them to find out why they have made the particular mistakes, how they can overcome such difficulties in future occasions, and improve new strategies. Due to these reasons, AH is considered efficient for self-study use (Soboleva & Tronenko, 2002, p. 483). Additionally, if learners are instructed about which strategies they need to follow in which situations, they can be directed and guided (Debski & Gruba, 1999, pp. 219-20). Similarly, learners' attention can be directed to metacognitive strategies such as planning, directing attention, self-monitoring, self-evaluation and similar strategies which are effective for exploitation of the facility itself. This is important because learners can be taught to "use appropriate comprehension strategies" (Goh, 2000, p. 71) and it is mostly needed during self-study, as learners are by themselves (Debski & Gruba, 1999, pp. 219-20).

AH can qualify learners to overcome potential sources of difficulties in the context of learning

any subject. For example, while learning a foreign language, unfamiliar items, proper names, syntax, fast speech, and unfamiliar accents can be taught more efficiently (Tschirner; 2001; p. 306). For instance, the meanings of unfamiliar items can be provided through hyperlinks or glossaries. These can be explained in through synonyms or antonyms. Likewise, learners' attention can be drawn to cognates, false cognates and polysemous words, which are useful for vocabulary acquisition and helpful for understanding, and improving listening and other skills (Vidal, 2003, p. 80). Additionally, simple sentences and short paragraphs featuring unknown items can be provided. In some cases, they can be explained throughout visuals, audio, video or optimum combinations. Their equivalents in first language can be given if learners are monolingual. Unfamiliar proper names can also be given in advance so that learners will not have difficulty. Such names can be given through pictures/cartoons that have labels and instructions. Similarly, cultural differences, syntax and lexis can be illustrated through simple samples, pictures, audio or video clips (Turel, 2014c, Turel & Kılıc, 2014).

Equally, while studying a different culture, religion, geography, science or any other topics, the pertinent input and relevant features such as cultural difficulties, costumes, traditions, figures, shapes and the assumptions underlying them can be presented and taught more efficiently through providing customised/adapted and combined comprehensible input and interactive tasks with instantaneous feedback.

Adaptive Hypermedia Provides Efficient and Instant Feedback

In CMs, feedback is normally given in learner's books or answer-key books. When learners have difficulty, they can access them. Although this is useful, it is very limited, as (a) it is not instant and (b) it consists of restricted elements such as text, pictures and graphics. In AH, feedback

is (a) immediate, (b) can consist of different elements, which meet both learners' visual and acoustic needs resulting in learning and (c) can be conditional/adapted. Such feedback can help learners to find out what and why they could not understand and overcome the difficulties causing them not to comprehend, which facilitates meaning negotiation (Williams, 2001, p. 337; Smith, 2003, pp. 39-40), draws attention and raises conscious/metacognitive awareness. This can guide and lead learners to develop new and effective strategies, which is one of the targets that material writers want to, and need to, fulfil especially in autonomous materials. This also draws learners' attention to the input, which is necessary for learning (Nicholas, Lightbown & Spada, 2001, p. 721; Williams, 2001, p. 335).

Adaptive Hypermedia Meets the Needs of Different Learners

It is a known fact that all learners do not have the same background and abilities. While some learners have high abilities and know quite a lot about target input/topic, other learners may not. It is also a de facto that not only do AH enable materials writers to make use of different elements, which can make input comprehensible and create gradual and different tasks, but it also enable material writers to adapt the learning contents to the needs of different learners who are diverse in terms of abilities, disabilities, levels, interests, backgrounds, and other characteristics. As a result, different learners can find what is most appropriate for them or a way of working which is most convenient for them. For example, learners with high ability can be provided with higher-level exercises and tasks, while those with low ability can be provided with lower-level exercises and tasks. Similarly, if some learners find audio/video clips too fast, then they can slow down the clips or alternatively they can be provided with the slow versions.

FUTURE RESEARCH DIRECTIONS

E

In spite of the above mentioned advantages of AH, many hypermedia applications on the market are not adequate. They contain certain features that are neither pedagogically nor psychologically sophisticated (Türel 2014; Turel, 2010, p. 399; Trinder, 2002, pp. 69-84). The problems fundamentally stem from hypermedia developers, not the pertinent technology itself (Turel & McKenna, 2012, pp.188-189) although technology has its own limitations, as well.

Therefore, AH applications need to be better developed. The pertinent findings in the field need to and ought to be fully implemented. For example, many AH applications do not feature proper self-assessment tests, although self-assessment tests are an essential element for learning especially during self-study. Similarly, AH applications need to give flexibility to learners. To overcome such shortages, we need to have more comprehensive and flexible AH evaluation criteria so that AH applications can be evaluated based on these criteria although some useful studies have been conducted to this end (Elissavet & Economides 2003; Ferney & Waller 2001). We also need to have enhanced AH development models.

AH should be fully integrated into education alongside CMs. It is striking that hypermedia is still not widely used (Turel, Calik, & Doganer, 2015a, Turel, Calik, & Doganer, 2015b, Turel, 2014a). Priority should be given to young learners, as they have more positive perceptions towards such technology (Türel, 2014). AH developers should further develop fully efficient AH applications in all subjects for all-level learners.

Future investigations need to develop better AH models, find out how to design each element as well as a whole more precisely, and improve efficient, comprehensive and flexible evaluation criteria. These will eventually result as a whole in creating ideal AH environments that facilitate learning.

CONCLUSION

Although AH has a vital role in learning, this is not the only issue that we need to be aware of. To ensure that AH plays its role in learning in true sense, efficient and fully adapted hypermedia environments need to be designed and created. Not only does this require the selection of the right input (i.e. in terms of age, level, contents and acquisition), but it also requires the adapted effective design of every single available element. These can only be achieved in true sense by the active and full participation of the pertinent experts (Turel & McKenna, 2013, pp. 189-190). Only such participation ensures that cost-effective AH can be created. These are very important and all have their role in the effectiveness of AH in education, the final aim of which is to enable learners to learn and acquire the necessary 21st century knowledge, skills and competencies.

KEY TERMS AND DEFINITIONS

Adaptive Hypermedia (AH): The combination and delivery of digital elements (i.e. text, sound/audio, visuals, animation, video, feedback, instructions, self-assessment tests etc.) on the same digital platform that adapts the learning contents to the needs of different learners who are diverse in terms of abilities, disabilities, levels, interests, backgrounds, and other characteristics.

Hyperlinks: A button, image, icon etc. in a digital environment on which learners can click to navigate to another part of the environment.

Hypermedia: IMM is also called hypermedia.

Hypertext: Hypermedia text retrieval system that enables learners to access particular media types in certain locations or files in applications, webpages or other digital environments.

Interactive Multimedia (IMM): The combination and delivery of digital elements on the same digital platform which have links between elements in the form of buttons, hotspots or hyperlinks to create an interactive application in which users can navigate.

Multimedia: The combination and delivery of digital elements on the same digital platform.

Multiple Media: The use of different tools such as television, the tape recorder, video, the overhead projectors, slide projector etc.

Automatic Item Generation

INTRODUCTION

As the importance of technology in society continues to increase, countries require skilled workers who can produce new ideas, make new products, and provide new services. The ability to create these ideas, products, and services will be determined by the effectiveness of our educational programs. Education provide students with the knowledge and skills required to think, reason, communicate, and collaborate in a world that is shaped by knowledge services, information, and communication technologies (e.g., Binkley, Erstad, Herman, Raizen, Ripley, Miller-Ricci, & Rumble, 2012; Darling-Hammond, 2014). Educational testing has an important role to play in helping students acquire these foundational skills. Educational tests, once developed almost exclusively to satisfy demands for accountability and outcomes-based summative testing, are now expected to provide teachers and students with timely, detailed, formative feedback to directly support teaching and learning. To meet these teaching and learning directives, formative principles are beginning to guide our educational testing practices. Formative principles can include any assessment-related activities that yield constant and specific feedback to modify teaching and improve learning, including administering tests more frequently (Black & Wiliam, 1998, 2010). But when testing occurs frequently, more test items are required. These additional test items must be

created efficiently and economically while maintaining a high standard of quality. Fortunately, this requirement for frequent and timely educational testing coincides with the dramatic changes occurring in instructional technology. Developers of local, national, and international educational tests are now implementing computerized tests at an extraordinary rate (Beller, 2013). Computerized testing offers many important benefits to support and promote key principles in formative assessment. Computers permit testing on-demand thereby allowing students to take the test at any time during instruction; items on computerized tests are scored immediately thereby providing students with instant feedback; computerized tests permit continuous administration thereby allowing students to have more choices about when they write their exams. In short, computers are helping infuse formative principles into our testing practices to support teaching and learning.

Despite these important benefits, the advent of computerized testing has also raised formidable challenges, particularly in the area of test item development. Educators must have access to large numbers of diverse, high-quality test items to implement computerized testing because items are continuously administered to students. Hundreds of items are needed to develop the test item banks necessary for computerized testing. Unfortunately, test items, as they are currently created, are time consuming and expensive to develop because each individual item is written, initially, by a content

specialist and, then, reviewed, edited, and revised by groups of content specialists (Gierl & Lai, 2016a; Rudner, 2010). Hence, item development has been identified as one of the most important problems that must be solved before we can fully migrate to computerized testing because large numbers of high-quality, content-specific, test items are required (Haladyna & Rodriguez, 2013; Webb, Gibson, & Forkosh-Baruch, 2013).

One promising test item development method that may be used to address this challenge is with *automatic item generation* (AIG) (Gierl & Haladyna, 2013; Irvine & Kyllonen, 2002). AIG is a relatively new but rapidly evolving research area where cognitive and psychometric modeling practices guide the production of tests that include items generated with the aid of computer technology. Research on AIG has adopted different perspectives, including the use of natural language processing and rule-based artificial intelligence (e.g., Gütl, Lankmayr, Weinhofer, & Höfler, 2011; Moser, Gütl, & Lui, 2012), frame-semantic representations (e.g., Cubric & Toasic, 2010; Higgins, Futagi, & Deane, 2005), schema theory (e.g., Singley & Bennett, 2002), and semantic web-rule language (Zoumpatianos, Papasalouros, & Kotis, 2011). The purpose of this chapter is to describe and illustrate the most practical method for generating test items, which is template based. By template-based AIG, we mean methods that draw on *item models* to guide the generative process. Gierl and Lai (2013, 2016a, 2016b) developed a three-step process for template-based AIG. In step 1, content specialists create a cognitive model for AIG. A cognitive model is a representation that highlights the knowledge, skills, and content required to generate new test items. In step 2, an item model is developed to specify where the cognitive model content is placed in each generated item. An item model is a template that highlights the variables in a test item that can be manipulated to produce new items. In step 3, computer algorithms place the cognitive content into the item model. With this process, hundreds of items can be created from a single item model.

The purpose of this chapter is to describe how AIG can be used to generate test items using the selected-response (i.e., multiple-choice) format. To ensure our description is both concrete and practical, we illustrate template-based item generation using an example from the complex problem-solving domain of the medical health sciences. The chapter is concluded by describing two directions for future research.

BACKGROUND

Gierl and Lai (2013, 2016a, 2016b) described a three-step approach for template-based AIG. In step 1, a content specialist creates a cognitive model for AIG. In step 2, an item model is developed to specify where the cognitive model content is placed in each generated item. In step 3, algorithms place the cognitive content into the item model.

Step 1: Identify Content for Item Generation

To begin, the content for item generation is identified by the content specialists. This content is identified using design principles and guidelines that highlight the knowledge, skills, and abilities required to solve problems and perform tasks in a specific domain. A cognitive model for AIG is a representation that organizes the cognitive- and content-specific information into a structured representation of how the content specialist expects that examinees will think about and solve problems. Recently, Gierl and Lai (2016b) proposed the *key features* cognitive model for AIG. With this model, item generation is guided by the relationships among the key features specified in the cognitive model. It is used when the attributes or features of a task are systematically combined to produce meaningful outcomes across the item feature set. The use of constraint programming in step 3 of the AIG process ensures that the relationships among the features yield meaningful items.

The key features cognitive model is most suitable for measuring the examinees' ability to assemble and apply key features within a domain as well as to solve problems using these key features.

Step 2: Create Item Models

In step 2, an item model is developed to specify where the content from the cognitive model must be placed to generate new items. An item model is a template that specifies the features in an item that can be manipulated to generate new items. Item models (LaDuca, Staples, Templeton, & Holzman, 1986) specify which parts of the assessment task can be manipulated for item generation. For a selected-response item type, it includes the stem, the options, and the auxiliary information. The stem is the part of an item which formulates context, content, and/or the question the examinee is required to answer. The options contain the alternative answers with one correct option and one or more incorrect options or distractors. Auxiliary information includes any additional material, in either the stem or option, required to generate an item, including digital media such as text, images, tables, diagrams, sound, and/or video. The stem and options can be divided further into elements. These elements are denoted as non-numeric values (i.e., strings) and numeric values (i.e., integers). By systematically manipulating the elements, many items can be generated from one item model.

Step 3: Generate Test Items Using Computer Technology

In step 3, computer algorithms place the cognitive model content specified in step 1 into the item model developed in step 2. Different types of software have been written to generate test items (e.g., Gütl et al., 2011; Higgins, 2007; Higgins et al., 2005; Singley & Bennett, 2002). Gierl, Zhou, and Alves (2008) introduced and demonstrated the use of the computer program IGOR (which is the acronym for **I**tem **G**enerat**OR**) for template-

based AIG. IGOR is a JAVA-based program designed to assemble test items using the items models from all combinations of elements specified in the cognitive model. Once the content is specified in step 1 and the template is created in step 2, IGOR systematically places the content into the template to produce new items as part of step 3. IGOR has been used to generate items in the content areas of mathematics, science, social studies, architecture, logical reasoning, dentistry, nursing, medical education, business management, and non-verbal reasoning.

The Unique Problem of Generation Distractors for Selected-Response Items

For the selected-response format, items must not only include a stem with a corresponding correct option, but also include a set of incorrect options or distractors. These incorrect options are typically designed from a list of plausible but incorrect alternatives linked to misconceptions or errors in thinking, reasoning, and problem solving. Using a traditional item development approach, a set of distractors are created by a content specialist that is specific to each item. But because AIG produces hundreds of items, an alternative approach is needed to create a correspondingly large number of plausible but erroneous distractors.

Three different methods can be used to generate distractors. The first method for generating distractors is often employed when the elements manipulated as part of the item generation process are first specified. Recall, elements are the variables identified by content specialist and then manipulated using computer algorithms to produce new items. A distractor can be specified as an element that contains content that is related to the correct option but still yields an incorrect response. To identify the content for this element, content specialists identify a list of plausible but incorrect options that are appropriate for all possible items generated with a given item model. Then, distractors are randomly selected from

this pool of plausible but erroneous content and added to each generated item. Hence, this method is called the *distractor pool method with random selection*. It is based on the assumption that a pool of plausible distractors can be created. A sample of these plausible distractors are selected at random to complete the item generation process. The strength of this method is its simplicity. This method can yield large numbers of distractors. The weakness of this method resides with the two strong assumptions required to use this approach. First, it must be assumed that all pooled distractors are equally plausible for all generated items. Equal plausibility is a strong and, in many cases, restrictive assumption. Second, there is little reasoning to guide how distractors are paired with the correct option because pairing is achieved with random assignment. The distractor pool method with random selection is most appropriate for case-specific item generation, where a well-defined set of distractors are known to be plausible across a large number of the generated item.

To improve the plausibility of the distractors, rules and rationales that yield errors or misconceptions can be used to create distractors. Distractor rationales are short description provided by the content specialist to ensure that the reasoning which underlies each option is explicitly stated. When rationales are available, distractors can be systematically generated such that each distractor matches with the rationale. Hence, this approach is called the *systematic generation with rationales method*. It is based on the assumption that algorithms, rules, and procedures can first be articulated by content specialists and then used to create plausible but incorrect alternatives. The strength of this method is that the distractors are much more specific and, hence, plausible and appropriate, especially when compared to the previous method. There is also a precedent for this approach as systematic generation using distractor rationale has been used in quantitative- and rule-based content areas, such as mathematics and science, to produce incorrect options (Haladyna

& Rodriguez, 2013). This method also has some weaknesses. For instance, plausible but incorrect rationales must first be created for each option by the content specialist. This process can be time consuming. Algorithmic or rule-based manipulations must also be permissible for every incorrect option. In some content areas and in some reasoning and problem-solving situations, generic rules or robust algorithms may not be available to guide the development of distractor rationales.

To overcome the weaknesses of the first two methods, a third method for distractor generation is also available. It is called *systematic distractor generation* (Lai, Gierl, DeChamplain, & Boulais, 2015). This method is closely linked to the cognitive modeling approach to AIG. Recall that to generate an item stem and correct option, specific information must be collected in the form of a cognitive model (i.e., step 1 in the three-step AIG process). The systematic distractor generation method also involves specifying information related to errors and misconceptions in the form of a cognitive model in order to generate plausible but incorrect options. The process of modeling incorrect options is more complex compared to modeling the correct option because the item stem is constantly changing in a generative item development system. As a result, the small number of constraints required to ensure that information presented in the stem yields a correct response must be counterbalanced with a much larger number of constraints required to ensure the information presented in the incorrect options is erroneous but plausible. Also, more than one incorrect option is required for a selected-response item. Typically, three, sometimes four, incorrect options must be produced for each generated item. Systematic distractor generation has many strengths. For example, it can be used in diverse testing situations and across many content areas because of its generality. It is also an adaptive method because distractors are selected conditionally using the associate information in the stem and the correct option. Finally, the features that lead to the correct

and incorrect options are explicitly identified. This method also has weaknesses. Systematic distractor generation requires that specific information be collected for each distractor. Because selected-response items contain two or more incorrect options, this specific information is required for each item in order to model the distractors. Hence, it is a time-consuming method for generating the distractors because data must be collected from content specialists, these data must be structured for distractor generation, and then computer code must be written to assemble the content for each option in a selected-response item.

AN EXAMPLE FROM THE MEDICAL HEALTH SCIENCES

To illustrate the three-step approach to AIG, an example from the medical health sciences is presented. This example is drawn from the content area of general surgery where the examinee is required to diagnosis problems that could arise from a serious abdominal injury. This example uses a key features cognitive model with systematic distractor generation.

In step 1, a cognitive model for AIG is created. The model in this example was created inductively by asking two 3rd year surgical residents to identify and describe the information that would be used by a surgeon to solve two serious medical problems (i.e., splenic rupture and Grade 1 liver laceration) related to abdominal injury. Three types of information are specified in the cognitive model for AIG. This information is presented as separate panels in Figure 1. The top panel identifies the main concept or problem and its associated scenarios. In this example, the problem is abdominal injury. Two associated scenarios are splenic rupture (SR) and Grade 1 liver laceration (LL). The middle panel specifies the relevant sources of information presented with the problem. In this example, three sources of information were presented: History, physical examination, and laboratory results. The bottom panel highlights

the salient features, which includes the elements and constraints. The first component for a feature is the element. Elements contain content specific to each feature that can be manipulated for item generation. The second component for a feature is the constraint. Constraints serve as restrictions that must be applied during the generation process to ensure that content in the elements are combined in a meaningful way so useful items can be generated. For the Figure 1 example, five features (i.e., type of accident, hemodynamics, side, air entry, and Foley output) were identified across the three sources of information. Each feature specifies the elements and constraints. For instance, the type of accident feature has three elements, low speed, high speed, and motorcycle. These elements contain constraints. For example, splenic rupture is only related to the motorcycle accident (i.e., SR: Motorcycle) whereas the low and high speed accidents are related to the Grade 1 liver laceration (i.e., LL: Low, High).

In step 2, the item model is created (see Table 1). The item model contains the template that will be used to generate test items. It also specifies the elements for the features. Five features are included. The Type of Accident feature has three elements. The remaining four features—Hemodynamics, Side, Air Entry, Foley Output—all contain two elements. Taken together Figure 1 and Table 1 describe the content combinations required to produce the correct option in the cognitive model. Splenic rupture is the correct option, for example, when the elements are: motorcycle accident at highway speeds (Type of Accident), blood pressure is 75/35 and heart rate is 140 (Hemodynamics), left side (Side), good air entry and a large distended abdomen with guarding (Air Entry), and 100cc of bloody urine (Foley Output).

The same logic is also used to produce the incorrect options using the systematic distractor generation method. Distractor 3 is diaphragmatic rupture. This diagnosis shares some, but not all, of the elements with splenic rupture. For instance, a diaphragmatic rupture can be associated with the elements motor vehicle accident at highway speeds

Figure 1. An abdominal injury cognitive model

(Type of Accident), blood pressure is 75/35 and heart rate is 140 (Hemodynamics), and 100cc of bloody urine (Foley Output). But a diaphragmatic rupture is not associated with pain on either the left or the right side (Side) and does not necessarily display physical examination results related to air entry and abdominal pain (Air Entry), as presented in the cognitive or item models. As a

result, diaphragmatic rupture is a plausible but erroneous option because it shares some but not all of the features related to splenic rupture. The same logic used to code the elements in diaphragmatic rupture is also used to code pneumothorax, cardiac tamponade, and aortic rupture in order to produce a cognitive model for the incorrect options. Then, an incorrect option is selected from

Table 1. An item model for generating abdominal injury test items

Stem	A 25-year-old male is involved in a [Type of Accident]. Emergency Medical Services resuscitates him with 2L crystalloid and transports him to your tertiary centre. When he arrives his [Hemodynamics]. He has a Glasgow Coma Scale score of 14. He is complaining of lower-rib pain on his [Side]. On examination, he has [Air Entry]. [Foley Output]. What is the most likely diagnosis?
Elements	Type of Accident: 1: highway speed roll over 2: bicycle accident where he hits a barricade 3: motorcycle accident at highway speeds Hemodynamics: 1: blood pressure is 75/35 and his heart rate is 140 2: blood pressure is 140/90 and his heart rate is 90 Side: 1: left side 2: right side Air Entry: 1: good air entry and a large distended abdomen with guarding 2: good air entry, mildly tender abdomen, and no guarding Foley Output: 1: A foley catheter emits 100cc of bloody urine 2: A foley catheter emits 600cc of urine
Options	1: Splenic rupture 2: Grade 1 liver laceration 3: Diaphragmatic rupture 4: Pneumothorax 5: Cardiac tamponade 6: Aortic rupture 7: Epidural hematoma
Key	

this distractor model for inclusion in the generated item whenever it shares some but not all of the elements with the correct option.

In step 3, IGOR assembles the content specified in an item model, subject to elements and constraints articulated in the cognitive model for both the correct and incorrect options. Iterations are conducted in IGOR to assemble all possible combinations of elements and options, subject to the constraints. In the current example, IGOR generated 62 abdominal injury items. The model used in this example is comparatively small and is provided for illustrative purposes only in our chapter. Item generation in operational testing programs typically include 5-7 different features per model where each feature has 2-10 different elements thereby producing much larger numbers of items.

FUTURE RESEARCH DIRECTIONS

Two areas of future research are recommended. First, methods exist for developing cognitive models for AIG (Gierl & Lai, 2016a). But no methods exist for evaluating the reliability and validity of these cognitive models. While Gierl and Lai (2016b) described two different types of cognitive models, many more cognitive models will likely be identified as researchers and practitioners begin to generate items in different domains and content areas. Hence, future research is required to develop methods for evaluating cognitive models as well as for expanding on the types of cognitive models that can be used for AIG. Second, new methods should be developed that allows feedback to be produced as part of the generative process. That is, the solution and rationale should be produced for

the correct and incorrect options during the three-step item generation process. This outcome would require a significant modification to the current item models and IGOR software. The benefits, however, would be significant. Effective formative assessment permits teachers to identify students' problem-solving strengths and weaknesses so they can adjust their instruction to overcome the weaknesses (Quellmalz & Pellegrino, 2009). But a test must contain a large number of items with carefully selected incorrect options related to a single concept in order to pinpoint different types of weaknesses, problems, and/or misconceptions. Item generation could be conducted so the solutions and rationales for the incorrect options are *designed* from a list of plausible but incorrect alternatives linked to common misconceptions or errors thereby providing teachers with this type of pinpoint precision. Therefore, additional research should be undertaken to refine the item models and the IGOR software so solutions and rationales that provide teachers with specific feedback can be produced as part of the item generation process.

CONCLUSION

As the importance of technology continues to increase, countries require skilled workers who can produce new ideas, products, and services. The ability to create these outcomes will be determined by the effectiveness of our educational programs. Education provides students with the knowledge and skills required to think, reason, communicate, and collaborate in a world that is increasingly shaped by knowledge services, information, and communication technologies. Computerized testing will foster the development of this highly skilled workforce by helping students acquire these essential skills. Computers allow educators to administer tests more frequently so students can receive specific continuous feedback as they develop their skills. But when tests are given more frequently, a constant supply of test items is needed. Automatic item generation is a

rapidly evolving research area where cognitive and psychometric theories are used to constantly produce tests that contain items that are generated with computer technology. The purpose of this chapter was to describe and illustrate a template-based method for generating test items to address the challenging problem of rapidly and economically producing large numbers of high-quality, content-specific, test items required to support computerized testing.

KEY TERMS AND DEFINITIONS

Automatic Item Generation: A process of using item models to generate test items with the aid of computer technology.

Cognitive Model: A representation that highlights the knowledge, skills, problem-solving processes and/or content an examinee requires to answer test items.

Distractor Pool Method with Random Selection: A method for creating distractors when the distractors created from a list and then the list is used to randomly select plausible but erroneous content for each generated item.

Elements: Variables in the item model that can be modified to create new test items.

Item Model: A template that highlights the features in an item that must be manipulated to generate new items.

Key Features Cognitive Model: A model used to guide item generation based on the relationships

among the key features specified in the cognitive model, which include the attributes or features of a task are systematically combined to produce meaningful outcomes across the item feature set.

Systematic Distractor Generation: A method for generating distractors where specific informa-

tion related to errors and misconceptions is used to create plausible but incorrect options.

Systematic Generation with Rationales

Method: A method to systematically create distractors when rationales are used to produce a list of incorrect options.

Challenges in Developing Adaptive Educational Hypermedia Systems

Eileen O'Donnell

Trinity College Dublin, Ireland

Liam O'Donnell

Dublin Institute of Technology, Ireland

INTRODUCTION

Traditional educational hypermedia systems afford learners the “one size fits all” approach to learning (Brusilovsky, 2003, 2004; Chatti, Jarke, & Specht, 2010; Hsieh, Lee, & Su, 2013). In the “one size fits all” approach to learning each student in every cohort of students is given access to the same learning objects in the same way as every other student who is studying the same course. The learning objects or learning content stays static regardless of the learning requirements of different students.

The objective of Adaptive Educational Hypermedia Systems (AEHS) is to afford learners the opportunity to engage with learning content which has been specifically designed to meet the learning requirements of each individual learner by adapting the content and the user interface to suit the needs of a specific user. AEHS could be used in the education of learners at all stages of their education from junior school to post graduate level. AEHS could also be used in organisations for continuous professional development or training for compliance purposes, for example, first aid or manual handling. Software engineering for AEHS commences with a thorough study of the requirements of the proposed system. AEHS, as proposed systems, are very complex systems to design as the software engineer has to design a system to enable non-technical and technical educator authors to design adaptive learning courses for use by students. Therefore, the design and development of AEHS are very complicated, time

consuming, and expensive. This article reviews a few of the challenges encountered in the design and development of these complex systems and some of the challenges encountered by educators who propose to use AEHS with their students.

The background section of this article provides the reader with brief definitions and discussions on the concept of AEHS and positions AEHS in the larger research area of E-Learning or Technology Enhanced Learning. The main body of the paper outlines some of the challenges encountered in the development and use of AEHS including: the classification of different categories of learners; the sourcing of suitable educational materials or learning resources; gauging the impact that AEHS have on the learning experience of end users; and student access to open and editable user models/profiles. Followed by sections on the following: solutions and recommendations; future research directions and the conclusion.

BACKGROUND

“Adaptive hypermedia systems build a model of the goals, preferences and knowledge of each individual user, and use this model throughout the interaction with the user, in order to adapt to the needs of that user” (Brusilovsky, 2001, p. 87). AEHS build a model of each individual student, and use the information from this model to determine the adaptive learning experiences to be created for each student.

The following sections provide more information on AEHS and include definitions of the terms Adaptive Education (AE), Adaptive Educational Hypermedia (AEH) and Adaptive Educational Hypermedia Systems (AEHS). E-learning and Technology Enhanced Learning (TEL) pertain to various forms of teaching and learning through the use of technology (O'Donnell & O'Donnell, 2015) and access to the Internet. TEL in the context of this article can be used synonymously with E-Learning. AEHS is a form of E-Learning which goes beyond the “one size fits all” approach to E-Learning by adapting the content to suit the learning requirements of individual learners.

Adaptive Education (AE)

Adaptive Education (AE) can be defined as an educational experience that adapts to suit the learning requirements of each individual learner. The purpose of AE is to provide learners with learning resources which have been specially selected to suit their specific learning needs.

Adaptive Educational Hypermedia (AEH)

AEH is electronic content which can be used in the provision of adaptive education. Software developers and educational providers are continuously

exploring how technology can be used to enhance the learning experience of students.

In a study of AEH authoring tools, Gaffney, Staikopoulos, O'Keeffe, Conlan, and Wade (2014) suggest that “AEH authoring tools have however not been as successfully adopted as was initially expected” (p. 416). Further research is required to explore why AEH authoring tools have not been as successfully adopted as initially expected.

Adaptive Educational Hypermedia Systems (AEHS)

Adaptive Educational Hypermedia Systems (AEHS) are designed and developed to deliver adaptive educational experiences to students. Some examples of AEHS include: GRAPPLE (De Bra et al., 2012; Glahn et al., 2011); AHA! (De Bra, Stash, Smits, Romero, & Ventura, 2007; Knutov, De Bra, & Pechenizkiy, 2009); and ELM-ART (Weber & Brusilovsky, 2001). AEHS use many different mediums of electronic content. Hypertext is a section of online text or an online paragraph of information that has been embedded with links to other content. Hypermedia is electronic content which includes links to many different mediums of content as shown in Figure 1, such as: text; images; tables; figures; graphics; audio; video; animations; simulations; or games.

Figure 1. Hypermedia can be linked to many different mediums of content

The purpose of AEHS is to provide educators with the appropriate toolset to present learners with educational resources that have been specifically selected to suit their individual learning requirements. AEHS or Adaptive Hypermedia Systems for Education (AHSE) have the potential to facilitate personalised technology enhanced learning (Muntean & McManis, 2004). AEHS Authoring Tools (ATs) are created to enable non-technical educator authors to design and create adaptive learning resources.

CHALLENGES ENCOUNTERED IN THE DEVELOPMENT OF AEHS

The development of AEHS is a very difficult process (Baig, 2014). There are many challenges to consider when designing these systems. A few of the challenges are outlined in this paper but others do exist. AEHS are very complex systems because they are designed to be used by many educators and many students who will possess various different knowledge levels of the use of Information and Communications Technology (ICT). There are numerous considerations and challenges involved in designing and developing systems for use by non-technical authors. There are also several challenges involved in developing systems for use by technically competent authors who may require the affordance of complicated functionality. In addition, the designers and developers of AEHS

have to meet the challenges of facilitating the functionality required by educators who employ various different pedagogical teaching methods (O'Donnell, Lawless, Sharp, & Wade, 2015) and learning theories (O'Donnell, Lawless, Sharp, & O'Donnell, 2015).

Adding adaptive functionality to an educational system does not necessarily improve the system, sometimes the adaptive functionality can cause users to lose control of the system (Brusilovsky, 1996). Adding adaptive functionality to an existing Learning Management System (LMS) does not necessarily improve the students' learning experiences. The students may not understand why they are getting access to different learning experiences to those of their peers. And, the educators may lose control over the adaptive functionality resulting in the students not achieving the expected learning outcomes.

Instructional designers and academics require a number of skills to develop positive learning experiences (O'Rourke & Martin, 2011). As shown in Figure 2, some of these required skills may include: pedagogical knowledge (Hirumi, Appelman, Rieber, & Van Eck, 2010; Koh & Chai, 2014); critical and creative thinking (Baum & Newbill, 2010); knowledge of instructional development (Stes, Coertjens, & van Petegem, 2010); awareness of aesthetic principles (Yanchar & Gabbitas, 2011); experience in instructional design (van Rooij, 2010); competence in the use of ICT (O'Rourke & Martin, 2011); among others.

Figure 2. Some of the skills required to develop positive learning experiences

Figure 3. Some of the student characteristics that can be used to classify different types of learners

The skill set required and the challenges encountered will markedly increase as instructional designers attempt to develop positive learning experiences that are also adaptable to each learner's specific learning requirements.

The use of AEHS to support learners can pose challenges to learners with respect to cognitive load and self-regulated learning, Moos (2014) and Kuo and Huang (2009) proposed the use of scaffolding in the development of AEHS to support learners. In the design and development of AEHS both the academic users and the student users (learners) have to be considered and facilitated. This dual requirement increases the complexity in designing and developing AEHS.

The Classification of Different Categories of Learners

Classification of learners is necessary to inform adaptive E-Learning models (Musumba, Oboko, & Nyongesa, 2013). User profiles (Brusilovsky & Millan, 2007) are necessary to store the information collected on each user. Profiling the learners' present knowledge informs academics about the gaps in knowledge and the level at which this information should be focused (Ajmal, Hamidullah, Rahman, & Khan, 2011).

Classification can be based on various different student characteristics as outlined in Figure 3, including the following: level of knowledge (Musumba et al., 2013); learning styles (Akbulut & Cardak, 2012); cognitive styles (Lo, Chan, & Yeh,

2012); prior knowledge (Chen, Chen, & Sun, 2014; O'Donnell, Sharp, Wade, & O'Donnell, 2012); learning preferences (O'Donnell et al., 2012); cognitive ability (O'Donnell et al., 2012); navigational behaviour (Brusilovsky, 2007; O'Donnell et al., 2012); role playing behaviour (Peeters, Bosch, Meyer, & Neerincx, 2014); among others.

The Sourcing of Suitable Educational Materials or Learning Resources

Another challenge encountered in the development of AEHS is the identification of suitable learning resources or objects to be used in the system. Learning objects would also have to be classified to enable retrieval and reuse by AEHS. While educational materials are frequently made available freely online, these resources are available in a number of different formats and may not be easily adopted for use in AEHS. The sourcing of suitable learning resources to facilitate the creation of Adaptive Hypermedia Systems is labour intensive (Levacher, Lawless, & Wade, 2014) and sometimes it is simply not possible to identify appropriate learning resources to use. The creation of learning resources for use in adaptive systems is a time consuming and complex process (Nurjanah & Davis, 2012), labour intensive and expensive. A research study conducted by O'Donnell (2008) was undertaken to establish lecturers' views on the use of ICT in higher education. The study participants were lecturers from various disciplines within the Dublin Institute of Technology. 41 lecturers

participated in this study. One of the findings was that only 15% of the lecturers surveyed agreed that they had sufficient time to create E-Learning resources (O'Donnell, 2008).

Gauging the Impact That AEHS Have on the Learning Experience of End Users

It is very difficult to state the impact that adaptive systems have had on the learning experience of the end user (Mulwa, Lawless, Sharp, Arnedillo-Sanchez, & Wade, 2010; Mulwa, Lawless, Sharp, & Wade, 2012) and “the jury is still out as regards evidence that ICT supports learning” (Livingstone, 2012, p. 19). The findings of Griff and Matter (2013) from the evaluation of LearnSmart (an adaptive online learning system) was that it had no overall effect. Because it is very difficult to gauge the impact that adaptive systems have had on the learning experience of the end users it may be challenging to encourage more educators to engage with the time consuming task of creating courses using AEHS.

There is a need through controlled evaluations of adaptive technologies to gauge the value added to improving student learning (Shute & Zapata-Rivera, 2012). Brusilovsky, Karagiannidis and Sampson (2004) proposed a layered evaluation approach be used when evaluating adaptive learning systems. Until AEHS are used in mainstream education the full impact of adaptive courses on the learning experience of students cannot be evaluated. Further investigations are necessary to gauge the impact that adaptive systems have on the learning experience of end users (learners, students, trainees, employees).

Student Access to Open and Editable User Models/Profiles

Adaptive systems gather some of the data to be stored in the user model by tracking a user's engagement with the adaptive system (Brusilovsky et al., 2008). Some adaptive systems automatically

update the user model so that the user never sees the changes made to their personal user model. In addition, in some adaptive systems users are not given the opportunity to edit their own personal user model for fear it will interfere with the personalisation processes of the system. Ahn, Brusilovsky and Han (2015) state that many arguments have been presented “in favour of open and editable user models” (p. 202).

Another challenge to the developers of AEHS is whether or not to provide the functionality to afford educators the opportunity to enable the users to see and edit their own user model. Some educators may be in favour of allowing their students to see and edit their own user model, while others may prefer to keep control of the user models through system generated automatic updates. In a study of self-regulated personalised learning, Steiner, Nussbaumer, and Albert (2009) found that “Up until now, the structures and algorithms underlying personalisation have been completely kept back from the user. The learner is completely unaware of the personalisation process that is taking place behind the scenes...” (p. 650).

In a survey of forty academics conducted by O'Donnell, Sharp, Wade and O'Donnell (2012) in response to the question “Would you trust the decision making algorithms in an authoring tool to determine the most suitable learning activities for each individual student?” (p. 9), only 10% of the academics surveyed responded “yes” to this question. Further along in the same study, O'Donnell et al state “The fact that only 10% of academics surveyed would trust the decision making algorithms is a finding of statistical significance that requires further investigation” (O'Donnell et al., 2012, p. 16). If academics find it hard to trust the decision making algorithms there is a possibility that learners would also like more information about the structures and algorithms used to determine the personalisation process.

Ashman, Brailsford, Cristea, Sheng, Stewart, Toms and Wade (2014) suggest that users should be informed about the personal information that is being collected and how this information is

Figure 4. AEHS are complex systems to design and develop

used in educational and other settings. In a study conducted by Staikopoulos, O’Keeffe, Rafter, Walsh, Yousuf, Conlan and Wade (2014), 30.6% of the students surveyed wanted more control over the content selected by the personalised course.

The amount of control to be allocated to the user of the personalised systems (Parra-Santander & Brusilovsky, 2015) and the right of the user to edit their own user model (Ahn et al., 2015) pose further challenges in the design and development of AEHS. The amount of control allocated to the user and the right of the user to edit their user model require further investigation to establish some guidelines for those challenged with the development of AEHS. AEHS are complex systems to design and develop and present many challenges as illustrated in Figure 4.

SOLUTIONS AND RECOMMENDATIONS

Designers and developers of AEHS require further feedback from the academic community and student body to inform future developments of AEHS authoring tools. Instructional designers and developers of E-Learning courses require additional supports and encouragement to engage with AEHS authoring tools. Further evaluations of existing adaptive courses are required to gauge the

impact that adaptive courses have on the learning experience of students to inform the designers and developers of AEHS and the educators who design and develop adaptive courses.

FUTURE RESEARCH DIRECTIONS

Further research is required to explore why AEH authoring tools have not been as successfully adopted as initially expected. AEHS are not yet sufficiently developed for use by non-technical authors. Further work is required on the development of AEHS. Further investigations are necessary to gauge the impact that adaptive systems have on the learning experience of end users (learners, students, trainees and employees). Further investigations are also required into the amount of control that should be allocated to the end user, and the right of the user to see and edit their user model/profile.

CONCLUSION

AEHS are very complex systems to design and develop. While the concept of AEHS is very promising, the realisation is very challenging, expensive, and time consuming. Some educators feel that they have insufficient time to engage in

the creation of e-learning resources while others feel that they could not trust the decision making algorithms which determine the most suitable learning resources to present to each student. The challenges encountered in the development of AEHS are many and varied as outlined in this paper. Further research is necessary to investigate the true potential of AEHS.

KEY TERMS AND DEFINITIONS

Adaptive Education (AE): The purpose of Adaptive Education (AE) is to provide learners with learning resources that have been specially selected to suit the specific learning requirements of each individual.

Adaptive Educational Hypermedia (AEH): Electronic content which is used in the provision of adaptive education.

Adaptive Educational Hypermedia Systems (AEHS): Systems that provide educators with

the appropriate toolset to present learners with educational resources that have been specifically selected to suit their individual learning requirements. AEHS are designed and developed to deliver adaptive educational experiences to students.

E-Learning: Facilitating teaching and learning through the use of technology and access to the Internet.

Hypermedia: Electronic content which includes links to many different mediums of content, such as: text; tables; figures; graphics; images; audio; video; animations; simulations; interactive games.

Hypertext: A section of online text or an online paragraph of information that has been embedded with links to other content.

Technology Enhanced Learning (TEL): Learning which is enhanced through the use of technology and the Internet.

Computational Thinking in Innovative Computational Environments and Coding

Alberto Ferrari

University of Parma., Italy

INTRODUCTION

The concept of Computational Thinking has been discussed for several decades and in recent years has been brought to the attention of the scientific community by Jeanette Wing. Her article presents Computational Thinking as “a way of solving problems, designing systems, and understanding human behavior that draws on concepts fundamental to computer science.” (Wing, 2006).

CT is a cognitive process involving logical reasoning that embraces the ability to think algorithmically using abstraction, decomposition and generalization.

The importance of CT places it among the basic skills for 21st century, together with reading, writing and calculation, that every person will have to master, so it is important to teach it already in primary school. As the invention of printing facilitated the spread of the three Rs (reading, writing and arithmetic) technology must lead to the spread of CT.

In our high-technological society teaching CT concepts in all level of instruction allows individuals to participate more equitably in society overcoming the differences now present in mastering these skills. Everyone should be able to apply computational strategies in each domain and understand what problems may be treated automatically.

CT is drawing fundamentally on concepts from computer science, it is not programming, but programming, meant as analysis and solution of problems, allows to highlight all CT features. Easy-to-use computational environments foster students in their first approach to coding and their use are becoming more common in school and university.

This chapter will introduce the research on CT and, in particular, the works on innovative computational environments, and will describe the situation of the education to CT in high school and in academic courses.

BACKGROUND

There is no single definition of CT and the following is the work of several authors who point out different aspects. A common feature is that CT represents a set of skills that are part of a cognitive process related to deal and seek solutions to problems. Abstraction, decomposition and generalization are common features of most of these works.

The term “Computational Thinking” was adopted for the first time by Seymour Papert, with reference to the LOGO programming language (Papert, 1996). According to his theory of “constructionism”, programming is a valu-

able educational tool that provides the cognitive artifacts necessary to the human mind to build a representation of the world with which it interacts.

“Think like a computer scientist” means being able to deal with a problem, to design a system and understand human behavior using the fundamental concepts and tools of Computer Science (CS). The power of our “mental” tools is amplified by the power of our “metal” tools (Wing, 2008).

There is still confusion over an acceptable definition for the term, in its essence, CT can be viewed as a re-foundation of “algorithmic thinking”. In the 1950s and 1960s, algorithmic thinking was understood as a mental attitude, enabling the description of a generic problem as a translation of some input data to output data, and the formalization of the required translation as an algorithm. CT is built on the same basis, with the inclusion of the ability to think about a complex problem at different levels of abstractions, to use mathematical methods, and to analyze data and the complexity of solutions, i.e., to study how a certain algorithm scales when the size of the problem grows.

CT can be defined as the ability to solve complex problems by applying the logic of computing paradigm; it is a set of cognitive skills, concepts and techniques of computer science related to problem solving.

In the 2010 workshop on “The Scope and Nature of Computational Thinking” participants developed a vivid discussion on what “CT for everyone” might mean. Wing describes CT as a bridge between science and engineering. Since it deals with thinking processes and abilities that can be applied to different disciplines, it represents a sort of meta-science. Moursund et al. (National Research Council, 2010) suggest a close relation between CT and Procedural Thinking, as developed by Seymour Papert in *Mindstorms* (Papert, 1980).

CT revolution goes much deeper than the use of computer in everyday work; it is changing the way we think. Among the features of the CT we find the ability to formulate a problem and

represent its solution writing an algorithm and compare the solution with others in order to assess its efficiency.

Another important feature is the ability to represent and organize data logically, using abstraction, generalization and modeling concepts, and identifying patterns within these.

Data abstraction, identification of common features and functionality comes into play both when we have to decide what to abstract and when we have to define the level of abstraction. The process of abstraction must then be followed by a process of analysis to verify the correctness of the assumptions and the quality of the result obtained.

Abstraction is probably the most significant process in CT: abstraction is used to define patterns, to generalize, to allow an object to represent many; abstraction allows you to extract common properties, to scale and then to deal with complexity; abstractions are the mental tools of computing.

Decomposition, the ability to decompose a problem into sub-problems of smaller size, is another important aspect. Decomposing a problem usually leads to the recognition of patterns and generalization, and therefore it also leads to the ability to design algorithms. Pattern recognition, the ability to identify similarities or common differences, is the basis of problem solving and algorithm design.

Generalization of pattern and abstraction allows to represent an idea or a process in general terms and then to be able to use this idea to solve other problems of the same nature. Algorithm design is finally the ability to develop a step-by-step solution for a given problem.

Bundy (2007) focuses, among other things, on the ability to process large amounts of data, Big Data, and describe a new model of science that defines e-science.

As we have seen, there are various definitions of CT and each one highlights certain features. A common factor among the various interpretations is the ability to solve problems using a systematic approach: problem solving.

The attitudes to be developed in order to reach the proposed objectives include the confidence to manage complexity and to deal with complex problems, the ability to address open problems and handle situations of ambiguity and the practice of teamwork and the burden of negotiating with colleagues to evaluate different proposals.

In the principal notes of the website “Exploring Computational Thinking” (Google, 2016a) Google asserts that CT is essential to the development of computer applications but at the same time it is an important factor to support problem solving across other scientific disciplines including math, science, and the humanities. Skills of CT allow students to identify a relationship between subjects as well as between school and life outside of the classroom.

CT concepts are present in various aspects that characterize Computing as a science and as a discipline. The concepts, techniques and informatics principles lend themselves as a starting point to educate to CT.

With the development of the CT trend, other views emerged. In particular, Denning (2009) argues that the term is neither unique nor representative of the whole of CS; he underlines the necessity of distinguishing CS from CT; the latter in fact includes only a part of the larger set of skills and knowledge possessed by a computer scientist.

After defining the fundamental principles and core practices of CS Denning ranks CT not among the fundamental principles but in the practices, and he defines it as a lens for looking at the world and interprets it as an algorithmic transformation from input to output information. According to Denning (1989, 2003), CS is a combination of engineering, mathematics, and science. In its essence, it can be described as the science of information processes.

CT can also be used to support problem solving across many disciplines, including math, science, and the humanities and is influencing research in nearly all disciplines, both in the sciences and the humanities (Bundy, 2007)

The term CT has also been used in the past and already in the 1980’s many scientists agreed

as computing was become a third leg of science in addition to theory and experiment so that the computation was essential for the development of the sciences.

Many are the examples of CT application in fields such as biology, chemistry, physics, Perkovic and Settle (2010) present examples of CT in more general terms and in all academic disciplines. Today we can talk about e-science, science that operates in distributed network environments and that uses high-performance computer on big data sets.

CT puts in relation the approach to the problems with the objective of proposing a solution that can be implemented on computer tools. The implementation is therefore closely linked to the use of programming languages. Coding is therefore one of the tools which are best suited to the teaching of the CT concepts.

INNOVATIVE COMPUTATIONAL ENVIRONMENTS

CT is not programming, but programming languages and coding are excellent vehicles for gaining access to basic concepts of CT.

Coding promotes the procedural thought and the process of decomposition, concepts that can be applied also in different contexts. Coding is only one aspect of CT but it is important as a medium to face fundamental concepts as abstraction, decomposition and the algorithmic approach to problem solving (Papert, 1980).

Villani (2015) underlines the value of coding as a basic educational discipline and describes programming languages and mathematics as “languages that help man in his struggle for the understanding of the world”.

Table 1 presents a list of computational environments adopted in project whose purpose is to introduce CT concepts through programming and problem solving.

Already in the 60’s Papert at MIT develops LOGO, a very powerful language that allows

Table 1. Computational environments

Project	Features	Interaction
LOGO	Easy-to-use programming language	Text
Scratch	Design and invent stories. Graphical manipulation of elements	Blocks
Snap!	Recursive blocks	Blocks
Alice	Storytelling in 3D environment	Sprites
App Inventor	Multimedia applications for Android devices	Blocks
Blockly	API. Engine for block application	Blocks

experts to create complex applications, but at the same time has a low threshold of access that allows its use even by primary school children. Mathematics, geometry and logic principles are learned easily through the turtle graphics; turtle, in the first version, was a robot moving on a surface via commands given through a computer. The spread of language and its use in education have a sharp increase in the years '80 thanks to versions of LOGO where the turtle was moving on the screen of a personal computer. Papert (1980), talking about his concept of constructionism, asserts that computer is an important simulation tool and that it is very important in education because it provides the fundamental cognitive artifacts for learning.

According to Papert program languages should be easy to get started ("low floor") and must give opportunities to develop complex projects ("high ceiling").

After a first period of great clamor in introducing coding concepts in education, the interest has gradually waned probably due to environments and languages too difficult to use in this context.

In recent years, there has been a revitalization of interest in introducing programming concepts since the early years of school. Consequently, to facilitate teachers and students, many projects started.

Scratch is developed by Michael Resnick and the Lifelong Kindergarten Group at the MIT Media Lab. Resnick (2009) presents Scratch as a tool for design, create, invent. Digital natives in most cases read but not write technology, so they need

to learn some type of programming to become creators of technology. In Scratch, programming is done by graphical manipulation of elements and not through the classical textual syntax. Users compose scraps of code, script, selecting predefined blocks and connecting them together to form a puzzle that represents the algorithmic solution of the problem. The ease of interaction with the environment makes it also suitable for children, but its use has spread in information technology introductory courses for students in high school and university (Brennan, 2013). Scratch sprites are an example of computer objects with various kind of characteristics, not only graphics ones. Characteristics and behaviors are defined by scripts and in Scratch is also present a simple message exchange mechanism. (Maloney et al., 2010).

Snap! is another programming environment that extends Scratch functionality allowing users to build new blocks (formerly his name was Build Your Own Blocks) and adding new capabilities, such as recursive blocks, which make it an environment aimed at a more advanced target such as high school students or university freshmen.

Snap! is implemented in JavaScript and this is a favorable aspect because it does not require any software installation as it works within any browser (Garcia et al., 2012).

Alice (Alice, 2016) is a 3D programming environment designed to be a student's first exposure to object-oriented programming. It allows students to learn fundamental programming concepts dragging and dropping graphic tiles to create simple

video games (Cooper et al., 2000). Bishop-Clark (2007) studied students using Alice in an introductory computing courses and found that they learn the programming concepts and gain a better appreciation of the complexity of programming compared with ones that start coding using text based languages.

The examples presented, like most projects for the diffusion of CT through coding, are based on graphical programming languages that give users the ability to build programs by composing graphical blocks together, to form a puzzle that represents the algorithmic solutions of problems. This approach, with respect to text-based programming, enables users to avoid issues of syntax and focus on the critical processes of designing, creating, and inventing.

The founding idea of block programming is to provide a graphical interface with blocks of diverse types. The user/programmer can combine the blocks in various ways through drag and drop operations, in such a way to form a puzzle representing the solution to a given problem. The blocks represent the basic elements of the language and they are differentiated by form and color, to easy their identification and usage.

Novice programmers must fight two battles in writing their first programs: the logical battle and the syntax battle. In environments based on block programming is impossible to introduce syntactic errors and this allows users to focus entirely on the logics of assigned problems and their solutions. In fact, the composition of blocks is rigidly constrained by existing slots, which represent the syntactic constraints of the language.

Most of initiatives prior described are directed specially toward primary school and they are based on ludic activities. The MIT App Inventor project (Wolber et al., 2011) is instead directed at a more advanced target. It is a block-based programming tool that enables the creation of simple multimedia application that can be executed on Android devices.

The Google Blockly environment (Google, 2016b) is built along principles similar to those

of the most widespread graphical language like Scratch (Resnick et al., 2009; Maloney et al., 2010), SNAP! (Garcia et al., 2012), MIT App Inventor (Wolber et al., 2011). Blockly is the engine running underneath many of projects that today propose block programming as the simple environment to introduce people of all ages to programming. There are now hundreds of educational projects that use Blockly library, the most important is probably code.org (Code.org, 2016): “Every student in every school should have the opportunity to learn Computer Science” is the opening sentence of this important project that involves tens of millions of young people (Wilson, 2014).

Although most educational projects and experiences proposing a block programming approach are oriented to a very young audience, projects directed toward high school students, like previous presented APP Inventor, are beginning to appear; in these cases, block programming is intended to help students get over the initial learning curve so that they can use more easily text-based programming languages.

Weintrop and Wilensky (2015, 2015b) compares conceptual understanding in block-based and text-based programming and through cognitive interviews and surveys to students found blocks-based programming to be easier because of the shapes and colors of the blocks, the drag-and-drop composition mechanism, and the ease of browsing the blocks library. Some points of strength and weakness are analyzed, as they are perceived by high school students which are allowed to move from a textual programming environment to a block-based one. Students identify the drag and drop composition interaction and the ease of browsing the language as contributing to the perceived ease-of-use of tools based on blocks-based programming. Being less powerful is indicated on the other end as drawback to blocks-based programming compared to the conventional text-based approach.

Price and Barnes (2015) in their study claim that block programming interfaces compared with text based ones can significantly improve novice

performance and understanding of fundamental programming concepts.

Starting from Papert's idea concerning programming languages, the evolution of the block programming can lead to broadening the horizon for applications of this type of language.

Ferrari et al. (2016) present a project that extends this visual paradigm to Object Oriented Programming.

Although, for complex applications, text-based languages will be more comfortable to use than those based on graphical syntax. Writing large programs in a visual programming environments is cumbersome, the same Google Blockly authors argue: "Please do not attempt to maintain the Linux kernel using Blockly".

After overcoming the first coding difficulties and when the programming concepts have been mastered, students should migrate to a conventional text-based language. For this reason, it is important already in the early examples to show the textual code, expressed in a conventional programming language, that correspond to the puzzle of blocks that represent the algorithmic solution of the problem.

Block-based programming environments are proposed as alternative way of teaching coding for novice programmers and are becoming increasingly common in introductory programming courses.

In addition to the discussion on the graphical or textual programming there is an important and unanswered question on which programming language is best for novices and what features make a language more or less accessible to beginners. Stefik and Hanenberg (2014) refuse the possibility of "One Language to Rule Them All" because of the variety of human perception and problem domains and even a perfect language, if it were created, may not be adopted. They present "the programming language wars" as a social ill causing problems in Computer Science discipline especially for new programmers.

COMPUTATIONAL THINKING IN HIGH SCHOOL AND ACADEMIC COURSES

Today, in schools and universities, only few specific courses are related to CT concepts. These concepts are, or should, be treated in "Information Education" courses.

Unfortunately for a long time, especially in high schools, CS has been considered only from the point of view of computer literacy, i.e., the ability to interact with computer systems and use specific programs.

The situation of Informatics education in Europe is not ideal. The title of a recent study, edited by ACM, is quite evocative: "Informatics education: Europe cannot afford to miss the boat" (ACM, 2013). It starts from the consideration that both governments and citizens in EU are conscious of living in a so-called "Information Society". But too often they satisfy themselves with the notion that learning to use digital media (i.e., digital literacy) is enough. Instead, digital literacy has to be considered as a very basic practical skill, and not an adequate intellectual tool for facing the new challenges.

To distinguish the more basic skills from the real science behind IT, the report adopts the term "Informatics", which is already common in continental Europe, but is acquiring the meaning of "Computer Science" also in the Anglo-Saxon world. Informatics is a scientific discipline that was born before actual computing machines, with the studies of Turing and Church in the 1930s. In the following decades, with its development into a full-fledged discipline, Informatics became an interesting mix of mathematical theory and electrical engineering, together with many seminal concepts of its own, including: algorithms; concepts of performance and complexity; data structures; concurrency, parallelism, and distribution; formal languages; abstractions.

The report summarizes its conclusions in few main points, which essentially underline and explain the need of education in both digital literacy and Informatics. Informatics is described as “a major enabler of technology innovation, the principal resource for Europe’s drive to become an information society, and the key to the future of Europe’s economy”. While some good progress is being made in teaching digital literacy, nevertheless more emphasis should be put on ethical issues, for a proper use of information technology resources. Instead, Informatics education, is sorely lacking in most European countries, and the situation is depicted as being worse than in the 70s and 80s. Without rapid changes, Europe will never be a major developer of information technologies, but a mere consumer, thus harming both its economy and the education of its new generation of citizens.

For achieving the desired objectives, the report advances some guidelines for the definition of new curricula. Those should take into account two main principles: “Informatics education must not just dwell on imparting information to students” and “it must draw attention to aspects of informatics that immediately appeal to young students, to encourage interaction, to bring abstract concepts to life through visualization and animation; a typical application of this idea is the careful use of (non-violent) games” (Overmars, 2004; Vassilev & Mutev, 2014).

CS researchers and professionals supported the idea of a more widespread diffusion of Informatics as a scientific discipline, with dedicated hours at least in secondary schools.

According to many reforms, elements of CS should be introduced since the first year in both technical schools and applied sciences secondary schools. In practice, however, the situation is changing at a very slow pace and possibly not improving, even with respect to Informatics.

An important research report (Google & Gallup, 2015) reports that in U.S. many students, parents and also teachers do not properly distinguish between computer science activi-

ties and general computer literacy; courses that school administrators consider to be computer science often lack programming. But another study by Horizon Media states that Americans now view computer science as a basic skill. 86% of interviewed say knowing how to use a computer is “just as important as knowing how to read and write.”

The importance of introduction of computer science in high school is that students who learn computer science in high school are 6 times more likely to major in it and computing occupations are now the first source of new wages in U.S. (Bureau of Labor Statistics, 2016). For this reason, in 2016 the U.S. administration is investing 150 million dollars in tech education projects to launch innovative training and placement models to develop tech talent as a way to keep and create jobs in local economies.

FURTHER RESEARCH DIRECTIONS

To overcome the ambiguity that has often led to regard computer literacy as the main objective of CT, research in this area is directed towards projects that aim at easing the learning of its core skills, while reducing the difficulties that students face in achieving these goals. Emphasis is on concepts and methodological approaches to problem solving, while coding becomes more and more a medium to achieve these objectives, not the ultimate goal. New educational development environments, as well as programming languages proposed, aim to drastically reduce the syntactic difficulty and to facilitate the first approach to programming and design (Kölling, 2008; Resnick et al., 2009).

Specific courses about CT concepts will increasingly be separated by CS courses, CT will become a specific discipline even if linked to more general IT aspects. In fact, ‘Computational thinking is influencing research in nearly all disciplines, both in the sciences and the humanities’ (Bundy, 2007).

CONCLUSION

The main aim of Computational Thinking is not to foster and simplify the development of applications. However, the proposals for new environments, tools and languages, which ease the first approach to programming, can be a starting point after which the other fundamental aspects of Computational Thinking, including abstraction and modeling, can be introduced. Their use will be specifically relevant in educational settings where students face at first the typical syntactic difficulties related with coding, but then they also have to deal with the more advanced challenges of design and testing.

KEY TERMS AND DEFINITIONS

Algorithmic Thinking: A method for solving problems based on the clear definition of the steps needed.

Coding: The process of writing, testing, debugging and maintaining the source code of software applications.

Computational Thinking: A method for solving problems mainly used for the development of computer applications, but that can also be used to support problem solving across all academic disciplines.

Constructivist Theory: An active process in which learners construct new ideas or concepts based upon their current/past knowledge.

E-Science: A computationally intensive science that either is accomplished in massive distributed network environments, or uses large data sets whose processing required distributed computing infrastructures.

Graphical Programming Language: A programming language in which the source code is itself graphical in nature and does not mainly consist of text. It is also known as visual programming language.

Computer Agent Technologies in Collaborative Learning and Assessment

Yigal Rosen

Harvard University, USA

INTRODUCTION

In recognition of the importance of collaborative and problem solving skills, educators are realizing the need for effective and scalable learning and assessment solutions to promote the skillset in educational systems. In the settings of a comprehensive collaborative problem solving assessment, each student should be matched with various types of group members and must apply the skills in varied contexts and tasks. One solution to these assessment demands is to use computer-based (virtual) agents to serve as the collaborators in the interactions with students. The chapter presents the premises and challenges in the use of computer agents in the assessment of collaborative problem solving and describes how human and computer agent collaborative assessments are used in international learning and assessment project Animalia.

BACKGROUND

Collaborative problem solving is recognized as a core competency for college and career readiness. Students emerging from schools into the workforce and public life will be expected to work in teams, cooperate with others, and resolve conflicts in order to solve the kinds of problems required in modern economies. They will further need to be able to use these skills flexibly with various group compositions and environments (Care, & Griffin, 2014; Griffin, Care, & McGaw, 2012; O'Neil, & Chuang, 2008; Rosen, & Rimor, 2012). Educational programs have focused to a greater

extent on the advancement of learning and the assessment of collaborative problem solving as a central construct in theoretical and technological developments in educational research (National Research Council, 2011, 2013; OECD, 2013a). Collaborative skills are included within the major practices in the 2014 U.S. National Assessment of Educational Progress (NAEP) Technology and Engineering Literacy (National Assessment Governing Board, 2013). In this assessment program, students are expected to show their ability in collaborating effectively with computer-based (virtual) peers and experts and to use appropriate information and communication technologies to collaborate with others on the creation and modification of knowledge products. Similarly, the Israeli national program of adopting the educational system to the 21st century illustrates a multi-year program with the goal of leading the implementation of innovative pedagogy and assessment in schools, including collaboration, communication, and problem solving (Israel Ministry of Education, 2011). Collaborative problem solving is one of the areas that the Organisation for Economic Co-operation and Development (OECD) emphasized for major development in the Programme for International Student Assessment (PISA) in addition to scientific, math, and reading literacy for the 2015 assessment. Collaborative problem solving refers to problem solving activities that involve collaboration among a group of individuals (O'Neil, Chuang, & Baker, 2010; Zhang, 1998). In the PISA 2015 Framework (OECD, 2013b), collaborative problem solving competency is defined as "the capacity of an individual to effectively engage in a process whereby two or more

DOI: 10.4018/978-1-5225-2255-3.ch209

agents attempt to solve a problem by sharing the understanding and effort required to come to a solution and pooling their knowledge, skills, and efforts to reach that solution” (p. 6). This definition; treats the competency as conjoint dimension collaboration skills and the skills needed to solve a problem. For the PISA assessment, the focus is on individual capacities within collaborative situations. Thus, the effectiveness of collaborative problem solving depends on the ability of group members to collaborate and to prioritize the success of the group over individual successes. At the same time, this ability is still a trait in each of the individual members of the group. Development of a standardized computer-based assessment of collaborative problem solving skills, specifically for large-scale assessment programs, remains challenging. Unlike some other skills, collaborative problem solving typically requires using complex performance tasks, grounded in varied educational domains, with interaction among students. These factors can affect the level of control that can be applied to ensure accurate assessment of students.

In this chapter, an operational definition of collaborative problem solving refers to “the capacity of an individual to effectively engage in a group process whereby two or more agents attempt to solve a problem by sharing knowledge and understanding, organizing the group work and monitoring the progress, taking actions to solve the problem, and providing constructive feedback to group members.”

COMPUTER AGENT TECHNOLOGIES

Collaboration can take many forms, ranging from two individuals to large teams with predefined roles. For assessment purposes, collaboration can also be performed using simulated agents playing the role of team members, using computer or humans as team members. Thus, a critical distinction is whether all team members are human or some are computer agents. There are advantages and limita-

tions for each method, which are outlined below. The Human-to-Human (H-H) approach provides an authentic human-human interaction that is a highly familiar situation for students. Students may be more engaged and motivated to collaborate with their peers. Additionally, the H-H situation is closer to the collaborative problem solving situations students will encounter in their personal, educational, professional, and civic activities. However, because each human will act independently, the approach can be problematic because of individual differences that can significantly affect the collaborative problem solving process and its outcome. Therefore, the H-H assessment approach of collaborative problem solving may not provide sufficient opportunity to cover variations in group composition, diversity of perspectives, and different team member characteristics in a controlled manner for accurate assessment of the skills on an individual level. Also, computer agent technology can contribute to efficiency in data collection by dramatically decreasing the assessment time with strategic dialogue management and rapid immersion in the collaborative context. Simulated team members using a preprogrammed profile, actions, and communication can potentially provide the coverage of the full range of collaboration skills with sufficient control. In the Human-to-Agent (H-A) approach, collaborative problem solving skills are measured by pairing each individual student with a computer agent or agents that can be programmed to act as team members with varying characteristics relevant to different collaborative problem solving situations. Group processes are often different depending on the task and could even be competitive. Use of computer agents provides a component of non-competitiveness to the collaborative problem solving situation, as it is experienced by a student. Additionally, if the time-on-task is limited, time spent establishing common ground or discussing non-task relevant work may lower group productivity. As a result of these perceived constraints, a student collaborating in H-H mode may limit significantly the extent to which collaborative problem solving dimensions,

E

such as shared understanding, are externalized through communication with the partner. The agents in H-A communication can be developed with a full range of capabilities, such as text-to-speech, facial actions, and optionally rudimentary gestures. In its minimal level, a conventional communication media, such as text via emails, chat, or a graphic organizer with lists of named agents can be used for H-A purposes. However, collaborative problem solving in H-A settings deviates from natural human communication delivery. The dynamics of H-H interaction (timing, conditional branching) cannot be perfectly captured with agents, and agents cannot adjust to idiosyncratic characteristics of humans. For example, human collaborators can propose unusual, exceptional solutions; the characteristic of such a process is that it cannot be included in a system following an algorithm, such as H-A interaction.

Research shows that computer agents have been successfully used for tutoring, collaborative learning, co-construction of knowledge, and collaborative problem solving (Biswas, Jeong, Kinnebrew, Sulcer, & Roscoe, 2010; Graesser et al., 2008; Millis et al., 2011). A computer agent can be capable of generating goals, performing actions, communicating messages, sensing its environment, adapting to changing environments, and learning (Franklin & Graesser, 1996). One of the examples for computer agent use in education is a teachable agent system called Betty's Brain (Biswas, Leelawong, Schwartz, & Vye, 2005; Leelawong, & Biswas, 2008). In this system, students teach a computer agent using a causal map, which is a visual representation of knowledge structured as a set of concepts and their relationships. Using their agent's performance as motivation and a guide, students study the available resources so that they can remediate the agent's knowledge and, in the process, learn the domain material themselves. Operation ARA (Cai et al., 2011; Millis et al., 2011) uses animated pedagogical agents that converse with the student in a game-based environment for helping students learn critical-thinking skills and scientific

reasoning within scientific inquiry. The system dynamically adapts the tutorial conversations to the learner's prior knowledge. These conversations, referred to as "trialogs" are between the human learner and two computer agents (student and teacher). The student learns vicariously by observing the agents, gets tutored by the teacher agent, and teaches the student agent.

A focused study has been conducted to investigate differences in student collaborative problem solving (CPS) performance in H-A and H-H modes (Rosen, 2014; Rosen, & Foltz, 2014; Rosen, & Mosharraf, 2015). Study participants included 179 students; age 14; from the United States, Singapore, and Israel. In all, 136 students participated in the H-A group and 43 participated in the H-H group (43 additional students participated in the H-H setting, acting as 'collaborators' for the major H-H group). Specifically in H-H assessment mode, students were randomly assigned into pairs to work on the CPS task. Because the H-H approach required pairs of students working together in a synchronized manner, the number of pairs was limited. This is due to the characteristics of technology infrastructures in participating schools. The students were informed prior to their participation in the study whether they would collaborate with a computer agent or a classmate. In a case of H-H setting, the students were able to see the true name of their partner. Students were exposed to identical collaborative problem solving assessment tasks and were able to collaborate and communicate by using identical methods and resources. However, while in the H-A mode students collaborated with a simulated computer-driven partner, and in the H-H mode students collaborated with another student to solve a problem.

The findings showed that students assessed in H-A mode outperformed their peers in H-H mode in their collaborative skills. Collaborative problem solving with a computer agent involved significantly higher levels of shared understanding, progress monitoring, and feedback. The results further showed no significant differences in other student performance measures to solve the problem

with a computer agent or a human partner, although on average students in H-A mode applied more attempts to solve the problem, compared to the H-H mode. A process analysis of the chats and actions of the students showed that in H-A group the students encounter significantly more conflict situations (e.g., disagreements) than in the H-H group. However, it was found that students in H-H setting were engaged in significantly more situations in which the partner proposed different solutions for a problem.

PROJECT ANIMALIA

An investigation to look further at the premises of human and computer agent technology in the context of learning and assessing collaborative problem solving skills was undertaken through collaboration between World ORT, the Ministry of Education in Israel, and researchers at Pearson. Animalia is an online mini-course designed to promote students' collaborative problem solving skills in the context of complex ecosystems (Bakken, Bielinski, Johnson, & Rosen, 2015). Animalia is a simulated fictitious village with a serious environmental problem. The fish in a local river are dying and the cause(s) of this problem is unknown. A team of scientists from an international organization (i.e. students) must determine the root cause of the problem and recommend sound, scientifically-based solutions.

The foundation of the problem-solving activity relies on understanding specific science concepts such as pH, oxygen saturation, nitrogen levels, the biological effects of pollutants, ecology, frog life cycles, algae physiology, as well as cause and effects in ecosystems. To create a more realistic scenario, team members will be given multiple and sometimes misleading, irrelevant, or contradictory pieces of information about what was happening in Animalia. It was up to the students to determine the authenticity of the data and to judge the credibility of the source. Each team member have had access to only some information about the overall

situation so that determining the root cause of the problems in Animalia require each team member to share his/her information with the others. Team members were encouraged to distill the information they receive into its essential components and to hypothesize what they think are the causes of the problem(s). Team members were also given feedback on each other's ideas and then form a consensus opinion. Finally, each team summarized findings and recommendations in a written report and an oral presentation. The teams described the cause(s) and provided recommendations to solve the environmental problems in Animalia. Learning was assessed through short quizzes and collaborative tasks. Additionally pre- and post-test of science concepts and collaborative skills were administered at the beginning and at the end of the mini-course. Collaborative problem solving proficiency was assessed at the beginning of Animalia through computer agent task ZooQuest (Rosen, 2014; Rosen, & Mosharraf, 2015).

The development team designed this mini-course to be completed in approximately 14 hours. Even though this is a collaborative task, due to the constraints of physical distance and time zone differences, students typically worked independently and communicate asynchronously (at different times) with their team members in other locations. The only two times students were online at the same time was when the teams discussed townspeople interview videos and gave their final presentations using Google Hangouts. Animalia content was provided in English, and English was spoken between partner schools. This gave students the real-world experience of collaborating with people from different cultures, with different levels of English proficiency, different levels of science knowledge, and across time zones. The content and related activities were provided online via a designated Moodle website. Each team have had its own "course" in the Moodle system which enabled team members to share information with each other, but prevented them from seeing information from other teams. Each session was available to students sequentially

during the project. When they logged in, students saw only those sessions that have been released up to that point. Across sites, teams were asked to stick to a common schedule so that all team members are progressing through the project work at the same pace.

Teachers play a key role in supporting this complex project. Teaching collaborative problem solving skills might be intimidating for teachers who typically deliver content-focused science instruction. But because these skills are fundamental to college and career success, teachers must help students improve upon these skills. Therefore, Animalia includes several professional development sessions to guide teachers on implementation of the course, as well as through the process.

Because students are working in teams from different time zones, teachers need to help coordinate schedules so that students are working on the same content at the same time. It is essential that teachers support and encourage their students as they progress through the sessions. Teacher's actions help students stay engaged and positive. There are times when the teacher will need to help your students troubleshoot any social or technical difficulties that may arise.

Student interaction within each group is necessary for successful completion of the task. Each student takes on a specific scientist role, and each role will gather its own unique information that must be shared with their team members to arrive at solutions or recommendations for the Animalia problem. It is important to emphasize this with students and be sure that each one understands what tools can be used to get connected and stay engaged.

Students must interact on discussion boards throughout the task. It is important that these discussions remain positive and on-task. Teachers monitor these discussions, and tell students so that they know you will be monitoring their progress. Students' awareness of their teacher's actions help prevent the posting of inappropriate or offensive remarks.

The study participants included 220 students, all 14 years old, from Israel, Italy, Bulgaria, Czech Republic, and Spain. The data were collected from February to April 2015. Recruitment of participating schools was achieved through collaboration with World ORT based on the following criteria: (a) population of 14-year-old students proficient in English, and (c) sufficient technology infrastructure (e.g., computers per student, high-speed Internet). In all, 108 students participated in low-CPS condition (i.e., low-CPS proficiency of all team members, as measured by CPS pre-test), and 112 participated in mixed-CPS condition (i.e., mid.-high CPS proficiency of two team members and low CPS proficiency among the other two team members). The students in both conditions were assigned to 4-person teams, two each from two different partner schools. No significant differences were found in science concepts pre-test scores between participants in the two groups. This similarity in student science knowledge allowed comparability of student results in Animalia between the two groups.

Preliminary findings indicated that students participated in a mixed-CPS condition significantly outperformed the students in low-CPS condition in their science concepts post-test, as well in the written report and oral presentation scores.

FUTURE RESEARCH DIRECTIONS

Team composition plays a significant role in collaborative settings (Kreijns, Kirschner, & Jochems, 2003; Nelson, 1999; Rosen, & Rimor, 2009). Collaborative problem solving performance is compromised to the extent that the division of labour is unintelligent, subgoals are not achieved, the group goals are blocked, and there are communication breakdowns. Collaborative problem solving tasks with high interdependency are very sensitive to group composition. One team member who has low competency can dramatically decrease the performance of the entire team and

force other team members to compensate in order to achieve team goals. An overly strong leader can prevent other team members from manifesting their talents. A meaningful collaborative interaction rarely emerges spontaneously, but requires careful structuring of the collaboration to promote constructive interactions. Incorporating collaborative problem solving assessment, as a tool for structuring student assignment to more optimal collaborative learning experiences such as Animalia is one example of potential use of computer agent based assessment. More research is needed to explore further these conditions and to more thoroughly understand their impact on outcomes. In this pilot, new insights were gained about collaborative problem-solving, but replications of this study will shed additional light and help to further inform the work of educators, researchers, and test developers who are motivated to help students discover and refine their own collaborative problem solving skills.

CONCLUSION

Students can demonstrate collaborative problem solving in tasks where assignments are distributed among team members, progress and results are integrated and shared, and products are presented jointly. Task structuring approaches aim to create optimal conditions for collaborative problem solving assessment by designing and scripting the situation before the interaction begins. It may include varying the characteristics of the participants (e.g., the size and composition of the group, or the roles), the availability and characteristics of communication and collaboration tools (e.g., the use of a phrase-chat or graphical tools), and the organization of the task. The collaborative problem solving assessment methods described in this chapter offer one of the few examples today of an approach in assessing collaborative problem solving skills. Collaborative assessments bring new challenges and considerations for the design of effective assessment approaches because they move the field beyond standard item

design tasks. The assessment must incorporate concepts of how humans solve problems in situations where information must be shared and must incorporate considerations of how to control the collaborative environment in ways sufficient for valid measurement of individual and team skills (Rosen, 2014). The quality and practical feasibility of these measures are not yet fully documented. However, these measures can rely on the abilities of technology to engage students in interaction, to simulate others with whom students can interact, to track students' ongoing responses, and to draw inferences from those responses. Group composition is one of the important issues in assessments of collaborative skills (Webb, 1995; Wildman et al., 2012). Overcoming possible bias of differences across groups by using computer agents or other methods becomes even more important within international large-scale assessments where cultural boundaries are crossed. New psychometric methods should be explored for reliable scoring of an individual's contribution to collaborative processes and solutions, such as stochastic and social network analyses, hidden Markov models, and Bayesian knowledge tracing (Soller, & Stevens, 2008; von Davier, & Halpin, 2013). Current research suggests that by using computer agents in a collaborative problem solving task, students are able to show their collaborative skills at least at the level of that of their peers who collaborate with human partners. Although human-to-agent interaction might not be regarded as equal to human-to-human collaboration, the advancing technology of computer agents makes the use of avatars a viable way to simulate collaboration, and this can offer researchers more control than is available with real human collaboration (OECD, 2013b; Rosen, & Wolf, 2014). However, each approach to assessment of collaboration still involves limitations and challenges that must be considered in the design of the assessments. Further research can continue to establish comprehensive validity evidence and generalization of findings both in H-A and H-H collaborative problem solving settings.

KEY TERMS AND DEFINITIONS

Agent: Either a human or a computer-simulated participant in a collaborative problem solving group.

Collaboration: Coordinated, synchronous activity that is the result of a continued attempt to construct and maintain a shared conception of a problem.

Collaborative Problem Solving: The capacity of an individual to effectively engage in a group process whereby two or more agents attempt to solve a problem by sharing knowledge and understanding, organizing the group work and monitoring the progress, taking actions to solve the problem, and providing constructive feedback to group members.

Computer Agent: An avatar with a preprogrammed profile, actions and communication. Computer agents can be capable of generating goals, performing actions, communicating messages, sensing environment, adapting to changing environments, and learning.

Problem Solving: Cognitive processing directed at achieving a goal when no solution method is obvious to the problem solver.

Cost-Effective 3D Stereo Visualization for Creative Learning

R. S. Kamath

Chatrapati Shahu Institute of Business Education and Research, India

R. K. Kamat

Shivaji University, India

INTRODUCTION

Technology-enhanced learning which has become a reality with the pervasive penetration of Information and Communication Technology (ICT) in almost all the walks of higher learning is by now not a new concept, but is still quite new in many educational institutions and settings. The pragmatic view by many researchers, first hand entails, that the chalk-and-talk environment is being both less and less relevant and effective to 21st Century digital age students, and does little or no justice to the learning of academically underprepared students (Dongale, Patil & Kamat, 2015). Especially in the domain of 'Engineering Education' it is clearly evident that Progress in computers and various technologies have changed traditional methods for teaching. Previously dominated by simulation and animation, now the educators are realizing that both the above said tools and techniques alone cannot substantiate true real-sense learning for users. This explores need for more advanced technologies in order to improve learning. In this context, the VR technology has found numerous applications in the field of education. The growth dynamics VR area reveals it's market size to \$407.51 million which will encompass more than 25 million users by 2018 (Marketsandmarkets.com, 2015). The main challenge of VR technology, however is the exorbitant cost due to the inherent sophisticated hardware and software which inhibits its inculcation in the education paradigm. In the backdrop

of above, we present a cost effective 3D stereo visualization system conceived, designed and developed by us for creative learning in the most cost effective manner.

The chapter is structured as follows: We open up with a brief overview of technology inculcation in education, which showcases the gradual progression from simple simulation and animation techniques to more sophisticated ones like VR. We also present the very notion of VR for the benefit of the broad audience of the chapter. The focus then shifts to the VR tool we developed, its system architecture, technical features and cost effectiveness. The manuscript then actually portrays setting the experimental environment for VR based pedagogy and thereby highlights its potential role in presenting the insight in realization of experiential learning in different domains.

BACKGROAUND: PROGRESSION OF EDUCATION TECHONOLOGY FROM SIMULATION, ANIMATION TO VIRTUAL REALITY

With the embryonic digital age, there has been intense discussion all over the globe, particularly in the last decade about the use of technology for personalizing the learning environment. VR is the fascinating area in computer application research (Vafadar, 2013). In recent years, 3D technologies in modeling, printing and stereoscopic have symbolized the true cutting edge in educational

systems (Dalgarno et al., 2010). The use of 3D glasses, stereoscopic 3D content and virtual environments in all curriculum areas to improve 21st century teaching and learning has been the buzz word in all the spheres of academics (Alpaslan & Sawchuk, 2004). The 3D in the Classroom has been clearly the winner over its 2D counterpart in improving the teaching-learning in the classroom. An interesting account of all these developments at the global level has been summarized in the following paragraph.

Pedagogic experts believe that merely theoretical explanation without actual implementation makes learning experience invaluable. Instead of listening only to lectures, if students get real experience in a virtual wrapper can achieve the learning outcomes. In this context VR is real winner and gained immense popularity in the education spheres. It provides a visually appealing technique for presentation of teaching material. It motivates student community by encouraging active participation rather than passivity. For example, a computer-based flight simulator in which pilots can attain flying skills in the absence of a real airplane ought to instill the right kind of skills. Many studies have been conducted on the applications and effectiveness of virtual Reality in education and training. Studies show that a virtual environment can stimulate learning because of it's a tight coupling between illustrative and experiential information (Hamada, 2008). Yahaya incorporated immersive VR technology in creating learning environment (Yahaya, 2004). His investigations indicate that learners gets engaged in real world problems associated with VR environment and it really helps in gaining the subject understanding. Elomar has explained the use of VR technology in learning environment through the 'experiencing of real phenomena'; new educational possibilities by the integration of education with VR (Elomar, 2012).

Dalgarno et al. have explained applications of 3D immersive virtual worlds in education and its implementation in education institutions across New Zealand and Australia (Dalgarno et al., 2010). The authors of the above referred study

have discussed overall research design with results from the Australian/New Zealand perspective. The main finding of this study is the variety of ways of using 3D virtual worlds by academicians.

Yet another paper by Piovesan et al., explained the application of VR in education. This research presents educational software, which permits students to manipulate objects in 3D with a simple interface (Piovesan et al., 2012). The software referred in the research is based on VRML for the design of models and PHP for web publishing. Manseur has discussed the use of VR tools and its applications in science and engineering education (Manseur, 2005). In particular, the VRML for model design is presented and subsequently the development of visualization tools for education has been depicted. Researcher has explained the combination of VRML with other software tools to create interactive VR solutions to support teaching and learning.

Teaching with 3D technologies is attracted by students' community as confirmed from research from case studies around the world. Learning accompanied with 3D video, interactions and simulations in virtual environment is attaining significant increase in performance, retention, abstract concept mastery, and more.

Well known VR tools developed in this context are (engagingeducation.net, 2015):

- **3D Ladibug Document Camera:** A dynamic document camera that can show objects and manipulate them in 3D stereoscopic by using the 3D software and hardware
- **Presente 3D:** An add-on to Microsoft PowerPoint, using which students can attach 3D stereoscopic to their presentations
- **Kid Pix:** An image processing tool that can be used to create pictures and videos in 3D anaglyph
- **Hasbro My3D:** A nifty gadget that facilitates students to get the immersive experiences sensation like walking through the Solar System

- **3D Books:** Facilitating students understanding by both the pictures and the content in 3D

There is increasingly good number of domains apart from education where VR has been finding its applications. Diverse fields including psychology, medicine, neuroscience, and physical and occupational therapy, the ICT MedVR group explores and evaluates areas where VR can add value over traditional assessment and intervention approaches. Areas of specialization are in using VR for mental health therapy, motor and cognitive skills rehabilitation, assessment, and clinical skills training. (Medical Virtual Reality, 2015). VR is beginning to be used extensively in built environment education. 3D virtual environment can provide a rich, interactive and engaging educational context that supports experimental learning. (Nicholos et al., 2012) VR has also its impact in various fields like entertainment, manufacturing industries, military bodies in addition to education. In the field of education 3D graphics plays major role (Kamath & Kamat, 2013). 3D models are very useful to make acquainted students with features of various shapes and objects. Many games have been designed using 3D images that the user needs to intermingle with in order to gain knowledge of a certain lesson (Bowman et al., 2006). Interaction with models increases a user's curiosity and makes learning more excitement. Simulations and visualization of complex data can be extensively done by using VR. The VR Technology has the ability to assist in the teaching process too, enabling students to view and interact with concepts they are working in 3D immersive environment (Steinicke, 2009). The user makes use of VR hardware to move and explore within an onscreen virtual environment as if in reality moving within a place in the actual world. Though VR paves the way for enhancing the visualization ability thereby making its headway in growing number of niche domains in addition to education, still it has to overcome many challenges for its adoption as discussed in the following section.

Impediment in VR Adoption and Way Forward

E

As presented in previous section VR leads to number of benefits, but its adoption is easier said than done. Particularly its espousal in education is challenging due to number of factors such as the customization of the technology per learner's need, lack of apt skill set amongst the faculty who are mainly digital immigrant and catering the needs of the computationally intensive software centric applications with the equally capable hardware platform. However amongst the three main challenges, the cost barrier is the main factor inhibiting the growth of VR in education. We aimed towards the cost reduction without compromising the performance and designed a 3D visualization method, an important facet of VR for active learning (Kamath, et al., 2012). We attempted developing a cost effective technique for achieving VR based active learning environment. With a combination of inexpensive hardware and simple-to-use software, students can enjoy the excitement of eye-popping 3D visualizations by employing our software suite on their fairly low end personal computers. The visualization solution developed is capable to browse the ASCII files containing the details of objects and the corresponding 3D scenes are rendered. 3D stereo visualization is a prime part of our software suite that accounts for virtual reality. This visualization solution offers inexpensive 3D interface to learner. The details of the software suite are presented in the following sections.

STRUCTURAL DESIGN OF 3D VIRTUAL REALITY LEARNING ENVIRONMENT

Traditionally the models of 3D objects are designed in modeling software. Corresponding file holds the geometric information as well as topological information of the object. This results in to very heavy file size. Since the topological details of

object are not required for visualization, executing such files for stereo visualization mode leads to time-consuming operation on a general-purpose computer. We eliminated the computationally intensive part of the traditional systems by designing a visualization solution which parses the ASCII files generated by any modeling software and retrieves only the data sets required for visualization in order to get desired display. We explain the structural design of the suite in the following section with the help of system architecture, sequence of operations and the method of exploring 3D vision in virtual learning environment (Kamath & Kamat, 2010).

System Architecture

The block diagram of the framework is shown in the in Figure 1. The visualization tool developed displays the model for 3D visualization by executing following modules:

- Computer Aided Design (CAD) systems are the source of design data. The objects are designed in CAD are exported to ASCII format. Our tool uses these ASCII files such as Stereo Lithography (STL) and Virtual Reality Modeling Language (VRML) files as input.
- The inputted STL or VRML file is given for parsing. Parser retrieves the required dataset from the inputted file for the visualization. These dataset stored in the form of scene graph structures. 3D scene is generated by rendering scene graph structures with the help of OpenGL. Rendering, i.e. the process of displaying the objects on the screen is accomplished in this manner.
- The Visual C++ programming language platform is used for the development of the visualization tool. It acts as an interface for STL and VRML models in 3D visualization.

Figure 1. Proposed research architecture

Technical Features of ASCII Files

As mentioned earlier the models designed in CAD system are exported to standard ASCII file formats. Information of the respective model is stored in the form of list of triangles. Coordinates of triangle vertices and other details associated with display are included in these ASCII files. The software suite processes the STL and VRML files for rendering the object. STL file contains facet-based representation of solid objects. The code snippet of ASCII STL file is given in Figure 2. It defines the surface of an object with set of

Figure 2. Syntax of ASCII STL file

```

solid roueascii.stl

    outer loop
      vertex 3.500 -35.391 4.659
      vertex 4.034 -37.205 0.000
      vertex 3.835 -36.946 0.000
    endloop
  endfacet
  ...
endsolid
  
```

triangles. VRML is a scene description language (Carey et al.). It encloses all the details required for visualization of the model. Figure 3, shows the syntax of VRML file.

Sequence of Operations

A flow chart shown in Figure 4 explains the sequence of tasks implemented during the development of visualization solution.

The sequence of operations is as follows:

1. Initially the objects or models which are designed in CAD are exported into ASCII file formats which are input to this visualization tool. This tool imports the corresponding datasets and processes the same for visualization.
2. Inputted ASCII file is parsed and dataset required for display are retrieved by parser module. It results in to storage of model's details in structures for the next task.
3. Display structures are created during parsing. These structures contain set of triangles definition as well as other details related to the display of CAD model.

4. These scene-graph structures are displayed on the screen. Here OpenGL graphics tool is used for the display of objects.
5. The prime feature of the software suite is to provide a 3D stereovision system that allows user to explore datasets with cost effective way explained next to this.

Cost Effective 3D Visualization

Main feature of the software suite developed is cost effectiveness. The learner can view and interact with 3D visualizations in stereo mode with the help of fairly low cost red-blue glasses on a general-purpose computer. Thus the software suite achieves passive stereo vision (Wormell et al., 2007). This technique allows the perception of depth when viewed through colored red/blue glasses. Here left and right eye images are overlays in different colors and create a stereoscopic picture. The image component sent to brain by each eye with the help of a color filter and the result in three dimensions is interpreted by the brain. This is the less-expensive way of projecting in 3D, using a single digital projector (Zelle & Figura, 2004).

```

Figure 4. System development flowchart

Figure 5. Blended image for two eyes

We follow the time-parallel principle for the stereo vision solution. The principle is based on providing both eye views to the viewer at a time and for directing each view to the appropriate eye it uses optical techniques. This needs the viewer to use red-blue eyewear. Simultaneous presence of both images on a screen, thus a time-parallel method is achieved.

Colored filter over each eye results in one eye image which has been rendered in red and the other in blue. We use monochrome stereo images in the software suite i.e. the superimposition of left and right eye views which are in blue and red respectively. Single image is formed by combining left and right eye images. Figure 5 shows the above referred blending of images. The three-dimensional effect is perceived by viewing this blending through eyeglasses of corresponding colors but in a reversed manner. Thus the rendering has is

easy to achieved using simple image processing techniques and the same is less expensive.

EXPERIMENTAL SETUP FOR VR BASED LEARNING

As seen above thus the boundaries in traditional education can be broken by VR technology to create a world of imagination (Elomar, 2012). This requires time, effort and thoroughly intricate methods to fiddle with the technology for the learning purposes. As evidenced from our development, with the use of simulation and special hardware enables learners to occupy in a virtual environment. For the construction of a virtual reality system the need of special hardware and software includes;

Figure 6. VR based learning environment

1. **Virtual Reality Modeling:** This includes models of real world environments created using AutoCAD, 3Dstudio etc.
2. **Virtual Reality Software:** VR toolkits, software to support ample of applications.
3. **Virtual Environment:** Using display monitor and stereo glasses, user can view and interact with entities in VR environment. Stereo Glasses, allows the user to view true 3-D stereo depth of computer generated images. Gloves, allow the user to interact with virtual environment through finger control.

Figure 6 explains the VR based learning environment in education (Kamath & Kamat, 2011). Initially models are designed using CAD software. After the design the details of the model are saved as ASCII format. VR tool reads this file and presents CAD data in virtual space. A learner can visualize the 3D model by using this tool. Since VR is a computer simulation of a natural environment, interaction with a 3D model is more natural than 2D.

Left eye image drawn in blue is superimposed with right eye image which is in red. This superimposition when viewed through red-blue glasses the three-dimensional effect is perceived. Authors recommend the Red-Blue glasses the one shown in Figure 7 to perceive 3D effect. Figure 8 depicts the display of doubly rendered model in red and blue as output of the VR toolkit designed by us.

Figure 8. 3D stereoscopic display of an object

FUTURE RESEARCH DIRECTIONS

The assimilation of VR, simulation and pedagogy provides a natural guide for future research. We are currently working on integration of social networking and visualization suite to imbibe creativity in e-learning scenario. Thus the future research and our further work aim at realization of social classroom in a flipped mode with 24 x 7 availability, which will exploit collaboration, teamwork and creativity amongst the learners and facilitates them to learn on their own, at the pace they prefer to grasp. Coupling of our software suite to the social networking platforms will assist us to research on the learning behavior of the students from different perspectives such as social integration, working in team as well as motivational and inspiration issues towards grasping new concepts.

Following are the set of additional facilities that would increase the supremacy and usability of this software suite;

- Openly support other CAD file formats such as STEP (Standard for the Exchange of Product model data), IGES (Initial Graphics Exchange Specification) etc.
- Implement auto stereoscopic vision that is perceiving 3D effect without the use of any external interface
- Supporting interface for other VR devices such as head mounted display, data gloves, simulators etc
- Picking and selection of desired part of the displayed model
- Changing the display properties for the selected parts of a rendered model

We are also working on the optimizing the software suite for a smart phone environment especially with the Android OS. This will help the learners to use this valuable learning aid on a move.

SIGNIFICANCE AND CONCLUSION

Virtual Reality has a pivotal role in bringing in meaningful teaching-learning ambience in education and training. Research on educational applications of VR, shows that VR technology can significantly improve the effectiveness of teaching by allowing learners to experience theoretical knowledge. In addition, it nurtures imagination, innovation, problem-solving of the learners thereby harnessing their creativity. We presented in this chapter a cost effective 3D stereo visualization solution which has great potential in education for active learning. This tool can be executed on a fairly general purpose low end computing platform. Students have the benefit of learning in such a VR based environment since it renders the display in the most personalized manner and thereby inculcate experiential learning.

Major advantages of using such a virtual reality tool in pedagogy are:

- VR based learning promotes a learner's ability to conceptualize in a three-dimensional space, and provide a sense of achievement whilst doing so.
- It makes the learning environment easy to use, cost effective, and convenient for users.
- The learners can study and test theoretical details in a virtual environment. Relevant information conveyed to students more efficiently than traditional techniques with the help of depth perception.
- VR has the prospective to revolutionize and improve the ways in which students are trained.
- VR grabs and holds the attention of students. It allows extreme close-up examination of an object.
- Engineering students can use less expensive projection or flat screen desktop stereoscopic solutions for 3D visualization and interaction in virtual environment (Sampaio et al., 2010)
- Medical students can learn spatial cues and sense of depth using Z co-ordinate while viewing material (Al-khalifah et al., 2006)
- Stereoscopic 3D Visualization has its impact in almost every area in education (Nicholos et al., 2012)

The development of this visualization suite was mainly an investigation on the technical practicality of a Virtual Reality System. We explored CAD as a medium to support early conceptual design through rapid prototyping of mechanical models. We thus explored Virtual Reality as a potential design prototyping environment in which prototypes of designs can be constructed, communicated and visually evaluated. The designed interface serves the visualization and evaluation of CAD geometry. Through a series of experiments, we thus implemented a method of achieving an

important feature of VR, stereoscopic display, in a cost-effective way for the most aspiring young learners. Interactive immersive less expensive 3D visualization of CAD object is the major outcome of this research which will no doubt yoke the creativity of the students who are now essentially digital natives. We are further working on coupling the software suite to the social networking platforms to experiment on the learning behavior of the students from different perspectives such as social integration, working in team as well as motivational and inspiration towards grasping new concepts.

KEY TERMS AND DEFINITIONS

OpenGL: A software interface to graphics hardware for displaying object on the screen.

Parser: A module receives VRML or STL file as input, extracts the required data sets for visualization and creates display structure.

Passive Stereo: An inexpensive technique uses red-blue eyewear to perceive 3D effect.

Prototyping: An early model built to act as a thing to be replicated.

Renderer: A computer program which makes an object appears on the screen.

Scene Graph: An arrangement of logical and special representation of a graphical scene.

Stereo Visualization: A computer generated scene viewed using stereo glass to get three-dimensional effect.

Three-Dimensional: A set of geometric three parameters height, width and depth which describes an image.

Virtual Reality: A computer graphics technology that offers a simulated three-dimensional world.

Could Educational Technology Replace Traditional Schools in the Future?

E**John K. Hope***University of Auckland, New Zealand*

INTRODUCTION

During a recent presentation, Professor Karen Willcox, Professor of Aeronautics and Astronautics and co-Director of the Centre for Computational Engineering at the Massachusetts Institute of Technology, showed a painting of a university classroom in the Middle Ages with a teacher on a podium at the front of a room lecturing to a group of students, one of whom was asleep. Her next picture was of a twenty first century classroom with a teacher at the front lecturing to students, some of whom appeared to be uninterested. Her point was that little has changed in university classrooms for centuries, yet the affordances of e-learning suggest that university education could change more in the next fifty years than any change in the previous five hundred years.

BACKGROUND

The scenario portrayed above is also visible in the compulsory schooling sector where the majority of compulsory education still occurs in classrooms with a teacher, but it could be argued that technology-induced change is already occurring. Information and communication technology has penetrated even the most remote schools in developed countries and is infiltrating schools in some of the least developed countries in the world. Futurists have predicted the demise of many brick and mortar universities resulting from the affordances of technology that allow learning to occur anytime, anywhere and in whatever format the learner desires. What of bricks and mortar

schools? The growth of virtual education is not limited to adult education, schools are already incorporating virtual education into their educational programmes and some parents are opting for home based virtual education in preference to traditional schooling. Marketing of educational technology has attracted some of the biggest names in business and the education market has become an important component of the world economy, so change is inevitable.

The presence of technology in a classroom should not be seen as an indicator of change in the learning process; the early use of computers in schools was merely replacing teacher instruction with computer instruction, termed programmed learning. In both cases the instruction was top down, based on the view that the teacher or computer programmer was the font of knowledge whose task was to deliver information for the student to memorise. This instructional process can be useful for the delivery of some learning, such as presenting factual information, but the exponential growth of knowledge resulting since the computer revolution began, and the ease of access to that knowledge via technology, makes knowledge transmission possible without the need for a teacher in a classroom. It is easier to keep a computer up to date with the latest knowledge than to keep a teacher up to date. So what is driving changes to the form of schooling as it has traditionally been known?

Changes to Schooling

Globalisation has changed the range of knowledge, skills and dispositions required for a satisfying and

productive life. Traditional employment areas such as book-keeping have all but disappeared, new vocations such as mainframe computer engineers were created and then outlived their usefulness, and the world economy has lurched from one crisis to another due to influences beyond the control of any one individual. Soft skills are now needed to compete in a rapidly changing world and education must adapt to meet these changes.

Learners have changed too. The so-called Generation Z students are now in compulsory schooling. There is a debate about the definition of Generation Z. Geck (2006) indicated that the term is used to describe the students who born in or after 1990, Shatto and Erwin (2016) stated that Generation Z follows the Millennials, while Seemiller and Grace (2016) said Generation Z's students were born between 1995 and 2010. According to Seemiller and Grace (2016), Generation Z students are "loyal, thoughtful, compassionate, open-minded, and responsible" (p. 8). Viewed from family perspectives, Seemiller and Grace suggest that the personality characteristics of Generation Z are unique, because Generation Z students are raised by Generation X parents with an emphasis on individual responsibility and independence.

Although the dates that define Generation Z may differ, scholars have reached consensus that the world of Generation Z is shaped by the internet (Bassiouni, & Hackley, 2014). Generation Z are the first generation to spend the whole of their life in a world dominated by social media use. Viewed from social media perspectives, a Pew Research Center (2014) study indicated that millennials are "digital natives—the only generation for which these new technologies are not something they've had to adapt to" (para. 7). They have more reliance on social media such as Facebook than their older generation. An example of the influence of the internet can be found by viewing YouTube clips¹ show Generation Z babies trying to flick pictures in paper magazines to enlarge the picture or turn the page, in marked contrast to earlier generations who knew to turn a physical page.

As with any new technologies, there can be positive and negative effects on people. Social media links make it easier to connect with other people anywhere, anytime, but can be addictive. Social media addiction is a recently defined psychological phenomena spawned by issues with teenagers who cannot be parted from their smart-phone for more than an hour and whose health and school performance can suffer as a result ². Generation Z students are now in schools, bringing with them different learning needs to those of the generations before them. Their social lives are heavily influenced by social media and they cannot see why use of social media should not be normal within their education. Again, education must adapt to the changed needs of this different generation of learners.

As the baby boomer and subsequent generations age, many become financially independent, have increased free time and can turn to education once again to enhance the quality of their lives. Adult learners are either well qualified people who want to study later in life for interest, rather than to qualify for a vocation, or they may be adults who left school before earning the qualifications needed for success in life. In both cases, adult students may look to study at secondary school level, not by physically attending school where they would not fit socially, but studying virtually. As a result, Scandinavian countries have led the world in providing pathways into education for the needs of these adult learners, including use of technology (Biagetti, & Scicchitano, 2013; Boeren, Nicaise, & Baert, 2010; Rubenson, & Elfert, 2015). Adult learners who were schooled decades ago need different approaches to meet their technology education needs (Roche, 2016) as many lack the background in technology of younger generations.

As globalisation has changed the nature of work, technology has influenced the nature of learning and learners themselves have changed, there is a need for schools to change. The affordances of educational technology are likely to drive this change, particularly with new forms of virtual education (Robinson & Aronica, 2015).

The Schooling of the Future

No one person can predict the future, least of all this author, but the remainder of this chapter is devoted to suggestions of what some scholars think the future of compulsory schooling might be, seen through the lens of educationally focused information and communication technology development. Four areas will be examined in the text that follows. The implications of social media for education, blended/virtual learning and educational gaming are learning strategies to be examined in detail, followed by the implications for technological education leadership in schools.

FUTURE RESEARCH DIRECTIONS

Social Media and Education

Social media such as Facebook, WhatsApp, Twitter, LinkedIn and the like are accessed daily by most adults in developed countries. According to Duggan's (2015) survey in the United States, 70% of Facebook users, 59% of Instagram users, 27% of Pinterest users and 22% of LinkedIn users visit these platforms daily. Social media have also gained dedicated followers in schools, firstly in secondary schools and now increasingly in primary schools, despite their use in schools often not being encouraged by school authorities. Facebook states that the age limit for users is thirteen years, yet recent research has found usage at elementary level to be common. For example, McDonald, Laxman and Hope (2015) found that most nine to 12 year old students used Facebook 'illegally' by mis-stating their age or sometimes supported by their parents/caregivers who allow their children to use their Facebook account, despite concerns about frequently reported issues such as cyberbullying, sexual exploitation and social media addiction. By their nature, social media software packages were designed for social use so their take-up by educators has been understandably limited. However some studies

have found that school students often used social media for education related purposes. Roblyer, McDaniel, Webb, Herman and Witty (2010) found that up to 50% of students communicated about schoolwork while online using social media, the implication being that when social media are an integral part of a student's social life, this affordance should be utilised for formal educational purposes (Baran, 2010).

Benefits suggested from social media use in education include encouraging students to engage more freely with their learning and feeling less constrained when talking about it (Tynes, 2007), sharing knowledge with other students (Mazman & Usluel, 2010) and facilitating more introverted students to speak up online where they would be reluctant to do so in a face to face group situation (Larkin, 2016). To mitigate the disadvantages of social media, including the likelihood of social distractions when using social media in class, educational social media sites are available such as Twiducate.com, Classroom 2.0, Ipernity and Ning. Being virtual, these websites work both in school and out of school, blurring both physical and time divisions between the outside world and the classroom. Future use possibilities already being explored include international social network collaborations between students to develop international understanding, acceptance of difference and building international friendships. Social media are often used at all hours of the day and night, obviating the time change difficulties and financial costs that dogged earlier synchronous attempts for students to communicate between differing time zones using telephone and television links.

Blended Learning and Virtual Learning

As noted above, despite predictions of the demise of some physical higher education institutions due to the rapid growth of virtual learning, most school students still learn in a face to face school environment. No futurist found in a recent literature

search predicted the demise of schools in the near future. While as yet unknown new technologies can suddenly arrive and change the world, as did invention of the internet, current trends suggest that the near future of schooling is most likely to be founded on increased use of blended learning, where students can receive complementary face to face to face and virtual instruction (Miron & Gulosino, 2016). One high achieving Pennsylvania school district has utilised blended learning so successfully that it is used as an exemplar in an Entrepreneurship and Technology Innovations class at Harvard Business School, this use of an education example at Harvard Business School being an indication of the close link between the future of schooling and future business. The blended model adopted in Pennsylvania facilitates a move towards the previously idealistic aim of one to one individualised instruction and has seen voluntary enrolment of 300 students in the first year climb to 1100 students in year three. Blended learning does not suit all students. Initial results of the Philadelphia project show that when compared with traditional classes, two thirds of the blended programme students improved more than the traditional peer group, but one third did not improve, or did not do as well (Davis, 2016).

Another indication of the future for virtual learning is the arrival of MOOCs (Massive Open Online Courses) provided tuition free courses in almost any subject imaginable by high ranked universities in many countries. Although not necessarily providing a recognised qualification there has been massive take up of these courses by adults, enrolment numbers being in the millions for MOOCs provided by top universities such as edX MOOCs provided by Harvard and MIT. Although take up is high, completion rates can be as low as 5%, the main problem stated as being student time constraints. Research into this issue has found that adult students are beginning to adapt to MOOC style learning by using the MOOC as an initial source to be supplemented by other resources, utilising only the portion of the MOOC relevant to their needs, and finding that the ability to pick

up small components of the course at different times helped in mitigating the time constraints of modern life (Veletsianos, Reich, & Pasquini, 2016). This research highlights the affordances of virtual education such as anywhere, anytime, affordances that are also applicable to schooling. A study of edX revealed that 39% of edX MOOC participants were teachers, either enrolling for in-service professional development or to help in their pre-service certification endeavours (Ho et al., 2015). AboutEdu Inc., a non-profit organisation listing MOOCs available for the school sector, lists 33 MOOC providing institutions available to elementary and high school students, and/or MOOCs providing professional development opportunities for teachers. AboutEdu Inc. requests for MOOC assistance came from many countries with USA, China and India being the countries most frequently requesting MOOCs, a graphic illustration of the increasing global ubiquity of virtual learning.

A report by the United States National Center for Education Statistics found that virtual and blended schools numbers were growing, despite some negative reports about their impact on student learning. 447 virtual schools were listed in 2013-14, attended by 262,000 students, with another 26,000 students attending 87 blended schools (Miron & Gulosino, 2016). This report noted concern that the graduation rate from virtual schools was 41%, from blended schools 37%, compared with 81% for all schools. Other concerns included high teacher: student ratios (35:1 for virtual schools, 32:1 for blended schools, 16:1 traditional public schools), and virtual school rolls included smaller proportions of minority and low-income students. Three quarters of the virtual schools were private schools, a major difference from the traditional school sector, making comparisons difficult. But this report and another from Stanford University that found cyber-charter schools had an “overwhelmingly negative impact” (Center for Research on Education Outcomes, 2015, p. 32) on student achievement suggests that private sector involvement in the virtual/blended school

development has not always produced positive results. The issue of the increasing trend towards for-profit schooling will be discussed further in a later section of this chapter.

One other component of blended learning is making rapid and seemingly more positive inroads to schooling, particularly in the United States. Open education teaching resources are free to teachers and no longer are limited to teachers sharing their personal planning and ideas on the internet. One example is EngageNY, a collection of materials published free by the state of New York. With 45 million downloads and in excess of thirteen million users, this customizable material is only one example of many that are helping teachers to cope with high workloads and increased accountability. Users of this particular resource are not limited to the United States. Although primarily aligned with United States education standards, their listed users include tens of thousands of teachers from the Philippines, Canada, India, United Arab Emirates and the United Kingdom (New York State Education Department, n.d.). Other open education providers such as UnboundEd (www.unbounded.org) are appearing, increasing the likelihood that open education resources will become even more popular in the future.

Gamification

Almost all school age students in developed and developing countries are aware of digital recreational games, and most play them at some point in their lives. The motivation effect, fun and challenge of recreational digital games such as Minecraft have universal appeal that prompts teachers to wonder if there are classroom applications of gamification that could improve learning. Ever since computers became common in classrooms more than 30 years ago, games have been used in classrooms. Beginning with very simple rote learning, drill and practice applications such as teaching basic mathematical facts with small electronic rewards, newer games are much more sophisticated and are increasing being seen as having potential for

school use. A large scale United States survey of 500,000 students, teachers and parents conducted by a non-profit organisation revealed that in 2015, 48% of teachers surveyed reported using games in the classroom compared with 23% in 2010, and the number of teachers using online videos had increased from 47% in 2010 to 68% in 2015 (Speak Up, 2015). Use does not necessarily equate to achieving improved learning, but the same survey found that 48% of teachers, 50% of high school students, 60% of elementary students and 40% of parents considered educational gaming a component of their ideal future school, suggesting that educational gaming is seen to have value in schooling. Students identified reasons why they saw value in educational online videos including the ability to watch again as needed, easier to understand, connected to the real world, fits learning style, easy to access on mobile devices and more engaging.

Not all results were positive. The Speak Up survey also revealed that teachers were reluctant to use digital learning, and needed professional development to enable them to make maximum use of digital learning, such as when to incorporate them into the learning unit and how to sort out the educationally useful from the plethora of low quality games available on the net. Education administrators were cautious about the use of educational gaming and few had planned appropriate professional development for teachers. Despite this caution, big-money developers are introducing game-based programmes designed to develop 21st century problem solving skills and having the potential use for more authentic assessment purposes, such as measuring skills less readily measured by traditional methods. For example, Microsoft has developed an education version of Minecraft that could be used in this way. At the 2015 American Education Research Association conference, presentations included studies that investigated the merging of physical movement with virtual understanding, understanding students' virtual thinking, and virtual gardening, examples of emerging technologies

that utilise digital learning to supplement more traditional learning methodology, blurring the lines between recreational play and school-based learning (Herold, 2015).

Pokemon Go, an app that is higher tech version of the traditional recreational game, is creating news headlines as it sweeps the world while this chapter is being written. The game requires users to get out into their community and connect the real world with the virtual Pokemon world. Some of the media headlines are negative, noting safety issues for students, the warring component and at higher Pokemon levels, the requirement to pay. Conversely, incredible levels of motivation are generated, students have to get out into their communities and there is a community educational component built into the game. This has also made educators think about the potential of the model for educational applications (Doran, 2016).

Hard research demonstrating the affordances of digital games is sparse, but a meta-analysis of digital game research for K-16 students investigated the cognitive, intrapersonal and interpersonal learning domains (Clark, Tanner-Smith, & Killingsworth, 2014). Overall, analysis of 57 studies showed the digital game studies analysed to be more effective in all three learning domains than the non-game instruction measured. The authors of the research note the difficulty in all such meta-analyses across different studies, the results cannot necessarily be generalised to all other situations, only to the situations measured in the studies considered in the meta-analysis. Nevertheless, this study is one indicator of the potential of digital game based learning, particularly for supporting higher order learning outcomes.

For-Profit Education

For-profit education was mentioned above due to its increasing move into the compulsory schooling sector. When 2015 annual global expenditure on educational technology hardware reaches US\$15 billion (Molnar, 2016), big business takes notice. Similarly, when virtual education creates ac-

cess to the learners of the world at the click of a mouse, big business takes notice again. For-profit education has proliferated far beyond the private international school model and coaching classes of paid education of the past, with millions of school students now paying for part of their education via virtual means. This growth suggests that for-profit education growth is not limited to hardware sales, it also encompasses delivery of education, but not always as effectively as claimed. Henry Levine from Teachers College Columbia sees for-profit education as a whole making more claims about effectiveness and cost efficiency than are justified (Gustke, 2010).

A sample of the issues that have accompanied the growth of for-profit virtual education were documented earlier in this chapter, but there are also some examples where for-profit education has been beneficial. Microsoft's launch of the education version of Minecraft is one example that is currently available free. For profit corporations donate money to facilitate research into the educational use of technology, or provide some of their products without charging. Corporations have the resources to front technological and organizational innovation (Carey, 2010). They may also close educational market gaps left by traditional education groups, and provide a second chance for students ignored by non-profit education (Chung, 2012).

Educational Leadership

Earlier generations of school leaders could focus entirely on curriculum and assessment issues, their only contact with technology being chalk and writing equipment. Today's school leaders still have to focus on curriculum and assessment, but ignore the influence of electronic technology on curriculum and assessment of student learning at their peril. Provision of the most appropriate hardware, selection from the plethora of software packages available and choosing virtual providers are new school leadership tasks. Parental demands for school access to the latest

educational technology, internet security issues and the critical need for educational technology professional development of teachers all concern school leaders of today and are likely to take even more of leaders' time in the future. A 2016 survey by the Education week Research Center found significantly more teachers finding tailored professional development conducted by sharing with other teachers, collaborative planning and having educational technology coaches available in their classrooms meeting their professional development needs better than traditional forms of professional development, such as read-made educational district and for-profit company provided professional development (Flanigan, 2016).

One example that should concern school leaders is a summary of several American surveys by credible organisations, such as the Council of Chief State School officers, which found high stakes test score results varied dependent on the type of technology used to take the tests (Herold, 2016). Overall, there were suggestions that higher scores occurred when desktop computers were used, lower scores when laptops were used and lower again scores when tablets were used. One reason suggested was screen size, but results were not definitive. This example illustrates the difficulties facing school leaders when trying to decide what is best for their students.

However technology affordances also increase the tools available to school leaders that will assist them to deal with these new challenges. One example is the John's Hopkins university partnership with a non-profit organisation called Digital Promise to provide free access to a tool that provides objective evaluation information about the efficacy of technological offerings to schools (Cavanagh, 2015).

CONCLUSION

This chapter began by quoting Professor Wilcox noting that little had changed in schooling over the past 500 years. In response, this chapter provides examples of how the world has changed due to glo-

balisation and e-learning becoming mainstream, the changing needs and aspirations of the current generation of learners and the rapid development of new technologies to assist learning. All of the examples quoted suggest that traditional face-to-face schooling will change.

Hauser and Koutouzios (2009) state "it is arguable that technology has had a greater impact on elementary and secondary school education during the last twenty-five years than virtually any other development in American society" (p. 245). As some schools in the present are already doing, most schools of the future will most likely need to embrace educational use of social media, blended and virtual learning and educational gaming as learning tools and may incorporate for-profit components into their offerings. Educational leadership will change, with much more focus on research justified use of educational technology and continuous professional development of teachers to enable them to cope with rapid technology instigated change. But none of the evidence reviewed here suggests that schools as such will disappear. The economic and social survival of nations depends on the quality of education of its people so some form of compulsory schooling will be needed, be it virtual or not. Perhaps Professor Wilcox's lecture in ten years' time will compare a medieval school with a virtual or partly virtual school, a clearly different learning environment minus a teacher at the front delivering factual knowledge.

KEY TERMS AND DEFINITIONS

Blended Learning: Traditional face to face learning combined with technology mediated instruction.

E-Learning: Any learning conducted via electronic technology (computers, smartphones and the like).

Gamification: Electronic video games designed for teaching and learning rather than purely entertainment.

Virtual Education: Another name for e-learning, but referring more to electronically aided learning conducted without any face-to-face components.

Development of Communication Skills through Auditory Training Software in Special Education

E**Eduardo C. Contreras***Autonomous University of Coahuila, Mexico***Isis I. Contreras***Saltillo Institute of Technology, Mexico*

INTRODUCTION

The primary function of language is communication and this is per excellence, of verbal nature; manifesting itself as the defining feature of men as a rational being capable of communicating through a system of signs (language) used by social communities. People with hearing loss do not have access to natural language, hampering their oral and/or written communication. Some of them have never heard any sounds; in others, the hearing loss appeared later, so they have the need for auditory therapy.

Hearing impaired individuals who have received a cochlear implant, as well as those who need to use an electronic device to improve their hearing, should receive auditory therapy to teach the proper use of the devices. Those who never had access to a proper hearing do not recognize the meaning of the sound, and must learn to associate the sound with its concept. On the other hand, people who had access to hearing have the problem of oral communication, so it is necessary to receive auditory training therapy and must attend therapy in a special education (Merzenich, Pandya, & Tremblay, 2005).

This paper presents a study in Saltillo, Mexico in 2014, which is intended to verify the development of communication for people with hearing loss using Auditory Training Software (ATS), which allows to develop listening skills in a motiva-

tional context and influencing positive behavior in training tasks. The ATS helps to develop the skills of identification of presence or absence of sound, identify and discriminate a syllable from similar pairs considering difficulty levels and distinguish individual words and sentences or phrases.

This ATS has been useful in the community as an important support educational tool for students and teachers, it goes beyond teaching materials because it becomes relevant in the teaching-learning process, appropriation of linguistic symbols, communication (oral and written), personal identity (auditory phonetic), among others.

However, the use of ATS should be customized according to the user profile considering their language, age, education, level of curricular and cultural competition, type and degree of hearing loss, type of disability, among others; the ATS development is complex, it is difficult to find freeware. Currently, there are several applications for Auditory Training (AT) in different languages and even some adapted to the educational needs of other countries, for example, from English to Spanish (Moore & Amitay, 2007).

This paper contributes with a description to develop an educational software created by students and teachers of Computer Science, as well as a teaching tool to assess the user's progress, useful for teachers of Special Education and an appropriate research method to the disciplines mentioned.

BACKGROUND

AT is necessary for the development of communication for people with hearing impairment. ATS has designed to help streamline the complexity of projects and tasks as well as facilitates team collaboration, to develop human skills (the ability to interact and motivate), understand concepts and develop ideas.

Some basic concepts of the subject are mentioned below.

- **Prelocution Deafness:** Hearing impairment is one that occurs before the child has acquired spoken language and for whom the development of speech and hearing may be affected in different ways.
- **Post-Lingual Deafness:** Hearing impairment that occurs after learning spoken language.
- **Phonetics:** The study of the sounds made by the human voice in speech; production by the speaker and reception / perception by the listener, (Llisterri, 1991, p.15).
- AT is the process to teach people to understand the meaning of sounds. During this training, auditory stimulation is provided

to people to learn, to identify, distinguish and conceptualize sounds.

- Auditory-verbal method is a process that uses multisensory rehabilitation methods such as Ling's oral phonological system, Calvert's Multisensory System and the Van Uden reflective Method.

In the AT, the application of the theory of phonetics is very important because it is the basis of our communication system. The AT process uses an experimental method consisting of three stages to achieve the goal of communication. This process is described below (see Figure 1). In the first stage it is necessary to differentiate the General Phonetics (production and perception of sounds) from Descriptive Phonetics (different known languages); it is important General Phonetics because it describes the communication process. The second stage is refers to the study of the sound production by the sender is the Articulatory Phonetic, the Acoustic Phonetics studies transmission and perception of the message. Finally, Perceptive Phonetics, studies hearing and perception of the message by the receiver also used in the synthesis and voice also recognition between human-computer. The application of

Figure 1. Phonetics in the communications process
Source: Prepared, 2016.

the knowledge of phonics to re-educate children or adults with language disorders is known as Orthophony; the medical discipline that is related to voice disorders is the Phoniatriy, lastly, the Audiology is focused on assessing whether there is hearing loss that involves lack of understanding of the message received by the receiver. Every single person, from birth, goes through this process, either naturally or with special training because of a deficiency in the process of communication.

The practice of auditory training in the 21st century is considered in terms of the collaborative, interdisciplinary research of neuroscience, cognitive science, and auditory science (Kricos & McCarthy, 2007). Since the last century there have been published manuals that provide methods and material with basic lessons to train people with hearing impairments, particularly those who use cochlear implants or hearing aids (Rochette, Pescheux, & Bigand, 2008). People who use a hearing device or a cochlear implant need AT (González & Torre, 2006). It is important to understand that even though a child uses an appropriate hearing device, calibrated and in good condition, will not have the same access to auditory information as a child who hears normally does.

The auditory-verbal approach used years ago was proposed based on a group of sequential and structured strategies that rely only on the sense of hearing to provide access to linguistic information. Generally, the educational intervention is performed as described by Pérez (2010), who mentions the necessary resources for training and appropriate intervention for children with various forms of hearing impairment. For this, various methods are used in the lessons proposed for training; generally, they provide material for contrasting sounds, recognizing sounds, sounds of the words, prayers and songs, and rhythmic patterns. Rochette & Bigand (2010) proposed a training program similar to the previous one, which has a variety of stimuli of auditory perception on cognitive operations in children with hearing impairment; it is based on the training of the cognitive operations in the perceptive processes.

The auditory verbal therapy has been currently provided with the support of the computer, as shown by the study conducted in Germany (Strehlow, 2006), which used computer-based methods in order to measure and train the temporary sound processing methods and the stimulation through phonemes in children with dyslexia, to develop skills for spelling and reading. In the study by Russoa, Nicola, Zeckerc, Hayesa & Krausa (2005) they observed that the influence of AT alters the neural structure of speech perception brainstem. They used perceptual AT software in nine patients clinically diagnosed with learning language-based.

In another study by Stacey, Raine, O'Donoghue, Tapper, Twomey & Summerfield (2010) to evaluate the effectiveness of using an AT software in eleven adults with cochlear implants, focused to discriminate vowels and sentences, they found higher significance in discrimination of consonants in speech. Toledo (2005) proposed the use of Speech Analyzer (Summer Institute of Linguistics), software that allows recording and analyzing speech sounds, as a possible tool for studying speech therapy by testing the pronunciation of the consonants in people with speech problems. The test showed that these people could perceive the phonetic accent before applying the rules of orthographic accent. At the University of Konstanz a German prototype to improve the ability to discriminate sounds phonemes and syllables in people with mild cognitive impairment and mild Alzheimer's disease; the effectiveness of this training program to mitigate or even reverse cognitive decline was assessed. Zhou, Sim, Tan, and Wang (2012), mentioned the effectiveness and efficacy of a game for mobile devices (MOGAT) in children with cochlear implant, to develop his musical ability was demonstrated. The discrimination of the tone in a pleasant, intuitive and motivating way was improved.

It is currently offered in the market a variety of educational software for the hearing impaired, as they are: "Computer-Assisted Speech Perception Testing" and "Training at the Sentence Level", or CASPERSent, which is a multimedia program

whose main purpose is the sentence-level speech-perception training and testing for persons with hearing loss. Another programs are similar to the previous “Tracking Computer Assisted Simulation” and “Computer Assisted Speech Training (CATS)”. “Computer-Assisted Speech Training (CAST)”, was originally designed for adults with cochlear implants, but it can be adapted for use with adult hearing aid wearers.

Other commercial programs that can be used for people with hearing loss are: “Seeing and Hearing Speech”, “Sound and Way Beyond”, “Sound Scape” and “Speech Perception Assessment and Training System (SPATS)”.

There are some apps that might help with Auditory Processing Disorder like: “Auditory Reasoning”, “Phonetic Birds”, “Auditory Memory Ride”, “Sound Match”, “Hear Coach”, “Auditory Processing Studio” and “Articulation Games”; these apps can also help with central auditory processing disorder (CAPD) or other related disorders (e.g., receptive language disorder or autism).

The studies previously mentioned have different approaches, some of them use similar methods to the one presented in this chapter, but they do not cover the specific needs of Special Education in México and the above applications are not in the Spanish language. For this reason it became necessary to develop an application that meets the needs of the region of Northeast, México.

MAIN FOCUS OF THE ARTICLE

The approach is to use an appropriate method to provide AT in special education schools for children with hearing loss who have the need to develop communication skills, as well as the use of auditory information to teach them how to use their residual hearing to build relationships in their community.

In the studied problematic, two important elements have been identified: Children with hearing loss and AT educators.

- **Children with Hearing Loss:** Prelingual hearing loss and deafness can occur from birth or childhood; it means that they have never heard a sound in their entire lives. The Greek philosopher Aristotle said “all those who are born deaf are also silent, unable to speak and to rise to abstract and moral ideas”. Consequently, these children have problems of communication and education because this deficiency does not allow the full development of communicative language skills, this due to the lack of association of the signifier and the signified from the linguistic symbol as they are not able to connect sounds with its meaning. This problem also causes deficit in vocabulary, altered articulation of words, delayed morphosyntactic structure, attention deficit, and a poor oral and written communication. These individuals need a specific and planned intervention to help them access education. It is important to use the verbal hearing oral teaching method that allows deaf children (with hearing aids or cochlear implants) to structure their thinking and to acquire an inner language, which is the main base of educational work.
- **AT Educators:** Most educators in public special education centers in México do not use the software as a teaching resource because they do not have specialized software available. The existing software is foreign (in English), and the one provided in Spain contains vocabulary and pronunciation different from the Mexican ones. Software developers in México generally focus on the commercial, because this is not considered profitable. Generally, public institutions of higher education are the ones support the development of educational software for various public schools through projects financed by governmental institutions. Another problem identified in educators is that most of them are unaware

of the proper use of the software and how to evaluate the learner with it. Generally, the educator traditionally continues using the audio-verbal method without the support from ICT's, showing an attitude of technophobia and resistance to change. Added to this, the computer equipment in schools is scarce or obsolete.

Research Method

The research method used in this project is described below; using a conceptual map the system is represented, the study elements are identified in it and with those the problem is defined as: Children with hearing loss need to receive AT according with their level of hearing, reinforced by visual stimulation and interactive tasks that increase their motivation, in order to develop their communication skills.

The elements to define the method of study are identified, which are shown in the following functional relationship:

Communication of a children with hearing loss = f (listening skills, AT software, learning behavior).

These elements are very important in developing the research method because they are variables that contain the hypotheses, the basis for raising objectives and the research questions.

Based on the above a synthetic table is generated (table of methodological consistency), as shown in Table 1.

From this it is checked whether there is correspondence between the variables that are going to related, and between the approach of the objectives and hypotheses, when correct, one proceeds to design the Consistency Matrix (see Table 2) based on the theoretical framework. This matrix will help us develop our instrument of evaluation and measurement of study in a methodical and systematic way (Rivas, 2004). One continues with the collection and statistical processing of data for the results of the study. The research is a study case of the explanatory, qualitative and quantitative type because it uses observation in the population sample.

Sample Description

The study was conducted at the Center for Multiple Attention "Benito Juárez TV", where 11 hearing loss children were selected from among

Table 1. Methodological consistency table, where are shown objectives, hypothesis, research questions and research variables

Particular Objective	Research Questions	Variable	Hypothesis
O1. To evaluate, through software, the development of hearing skills in verbal auditory processing method in the rehabilitation of persons with hearing impairment to enable them to acquire oral communication.	RQ1. How much can the software rehabilitate people with hearing impairment on the development and understanding of sounds, syllables and words, to achieve an acceptable level of communication?	Hearing ability	H1. The multimedia-learning environment improves the development of listening skills in individuals with hearing impairment to develop their communication.
O2. To verify that the use of ear training software is an adequate tool for verbal teaching method in oral communication.	RQ2. Do software elements; multimedia, user interaction, the tasks of the auditory-verbal method relate to communication skills?	Ear training software	H2 There is a positive relationship between software ear training and communication development.
O3. To explore the behavior of natural language learning in the individual with a disability when stimulated in the process of communication.	RQ3. With the stimulus presented in the multimedia educational software, to what extent does it influence attitudes, motivation and attention on learning to speak in the hearing impaired?	Learning Behavior	H3 If people with hearing impairments are stimulated through multimedia software; they present a positive performance in auditory learning to develop their communication skills.

Table 2. Methodological consistency matrix, where are shown research variables, factors, indicators and dimensions

Variable	Factor	Indicator	Dimension
Auditory skills	Sounds	Presence / absence	9
		Sound identification	8
		Sound discrimination	7
	Syllables	Identifying syllable speech	6
		Discrimination syllable speech	5
		Identifies / discriminates a syllable in cognate pairs	4
		Syllable comprehension	3
	Words	Identifies isolated words	2
		Identifies words in a sentence	1
Learning behavior	Behavioral attitude	Enthusiasm	5 - Always
		Interest	4 - Almost always
		Constancy	3 - Sometimes
	Motivation	Active participation	2 - Rarely
			1 - Never
	Attention	Timing	Minutes
Ear training software	Multimedia elements	Audio	5 – Very good
		Picture	4 - Good
		Video	3 - Regular
		Text	2 - Minimum
	User interface	Usability	1 - None
		Different skill levels	
	Auditory-Verbal Method	Manipulate interface objects	
		Interface consistent	
		Performs the tasks	
		Schedules the tasks	
		Stimulates the audition	
		Evaluates the progress

45 students in preschool and elementary school, aged between 4 and 12 years. The rest of them present intellectual disability. The therapy was given one hour a day, twice a week.

The Auditory-Verbal Method

In most special schools in México, the audio-verbal approach for the development of oral communication is used. It aims to ensure that each auditory handicap student acquires oral communication through the stimulation of the auditory pathway, thereby promoting and achieving high levels of intellectual development and social interaction.

The auditory-verbal method suggests an individual education according to the needs of each subject, along with periodic assessments of

progress in each subject, as well as hearing aid evaluation, calibration and proper management for those who make use of it and are subject to the auditory method (Cervera & Ygual, 1998); (Estabrooks, 2006). The use of this method in the classrooms is described below:

Level I: *Sound Level Consciousness.* The first requirement for AT is that the subject perceives the existence of sound, and to be able to differentiate between presence and absence of sound.

Level II: *Sound Alert.* The aim is that the subject is interested in the sound, to pay attention to it and locate it.

Level III: *Thick auditory discrimination.*

The aim is that the subject responds to the language in the undifferentiated period, i.e.; by the emotional tone and not the meaning, and that differentiates through hearing the sounds, noises, voice and language all its acoustic characteristics.

An auditory-verbal approach includes the use of a system of sequential and structured strategies that rely only on the sense of hearing, in order to provide access to linguistic information.

Auditory Training Software Description “AudiTS” for Developing Communication Skills

The instructor tells the beginning user that the training he will receive is gradual and that it consists on four modules. Text instructions are displayed on screen and then an image menu is shown to select the desired module. If the user has received this training before, he will give continuity to it selecting the appropriate module. See Figure 2.

The first three modules are presented in the following environments: animals (pet, farm, wild); transportation (land, air, sea); home; the street; nature.

In the first module the user identifies the absence or presence of sound to choose a subject of the aforementioned environments. The first two modules contain an additional menu to select an item in the group. For example, if the user selects “farm animals”, an image is displayed on the screen of the computer and AudiTS can produce a random sound corresponding to the image; the user must answer whether or not there is sound by clicking on one of two buttons (yes or no).

The software validates whether or not there was sound. If the user succeeds, a visual message is displayed congratulating him, and if not, he is prompted to try again with another image; he will press a “Next” button to continue with another object. A digital counter is displayed in the bottom right of the screen that shows the ratio of hits between attempts to meet the user’s progress.

In the second sound identification module, the user selects an item from the proposed environments. An image is displayed and a sound is played. For example, the image of a cat is displayed and a meow is heard, this is with the intention of associating meaning with the signifier. The training consists in knowing the common sounds at home, street and nature, as well as animals and means

Figure 2. The menu of auditory training software (AudiTS)

Source: Prepared, 2016.

of transportation. In this section AudiTS does not validate answers because the child also interacts with the instructor.

In the third module the discriminant is applied in the same environments as in the first module. A topic is selected, four images are displayed and a sound associated with an image is produced; the user must validate the significance of sound with the significant image by clicking on the proper image. The images displayed in groups of four are always random and there is correspondence only with the sound, which the user must learn. The software performs the same tasks as in the first module: validates response, it shows a success or failure message and displays user performance.

The fourth module is divided into two areas: identifying and discriminating one syllable and the ability to identify and discriminate isolated words and contained words in sentences or phrases. To provide training about syllables a video showing an instructor pronouncing various syllables of cognate pairs is displayed, considering levels of difficulty and reinforcing learning with a text showing the syllable at the same time. Isolated words are presented in a video pronounced by an instructor emphasizing their joint and relating its meaning with an image. The words contained in the sentences are also shown in a video, and they are reinforced showing a text on the screen to

highlight the word in the sentence. In this module the instructor validates the child's performance relying on the report template.

Description of the Evaluation Instrument

The template to assess the child's performance is constructed from the matrix of methodological consistency, as shown in Table 3. The instructor records the qualification that the child obtained in each session in the column for each indicator.

Results obtained after about 4 months of effective use of AudiTS during a school period of eight months, excluding vacations and holidays, (see Table 2 for interpreting the results).

In Listening Skill the average obtained in the sound factor is 7; for syllables, 4; for words, 3. Children learned globally 30% of the vocabulary contained in the application (30 of 90 words) obtaining better performance in sound recognition.

In the Learning Behavior mode factor obtained in Behavioral Attitude is 4; motivation, 5; and the attention period was increased from 3 to 15 minutes.

In the AudiTS variable, the average for the multimedia elements factor is 5; user interface is 4 and auditory- verbal method is also 4.

Table 3. Template where the therapist monitors progress of the person receiving the therapy

Indicator	Qualification						
Presence/absence of sound	6	7	5	6	7	5	6
Sound identification	6	5	6	7	6	7	6
Sound discrimination	5	7	6	7	6	5	6
Identifies syllables	3	4	3	2	3	4	3
Discrimination syllables	2	4	3	4	3	3	4
Identifies/ Discriminates a syllable in cognate pairs	3	4	2	3	2	3	4
Syllable comprehension	2	3	4	2	3	2	3
Identifies isolated words	3	2	3	4	3	3	2
Identifies words in a sentence	2	1	2	3	2	1	2
Words comprehension in a sentence	2	1	2	3	2	3	2

SOLUTIONS AND RECOMMENDATIONS

The solution presented modifies the traditional way of evaluating the child in therapy. The assessment tool is proposed to also consider elements, such as attitude, motivation and attention, as these are very important for a person to accept the therapy.

The template also suggests how to make the performance evaluation of a commercial computer program for AT.

The recommendations of the proposed solution are:

- The use of this software requires the supervision of a qualified person because it is a study that needs to evaluate quantitative and qualitative factors under observation.
- The software allows to evaluate the performance of the hearing ability of the user, but implies the need for the proposal template where the therapist monitors progress of the person receiving the therapy, which can be done manually or using a spreadsheet.
- The recommendation to use the software will reduce the technological gap in which these vulnerable groups currently are, and will be conducive to encourage the authorities and teachers in the use and benefit that it has IT in education and training.
- Another recommendation is to establish a link between the departments of computer science in public schools and special education for the development of educational software according to their specific needs.

FUTURE RESEARCH DIRECTIONS

The future trend in developing countries will not only bring the TIC's to the special education classrooms, but it will also be necessary to use information sciences mainly in the implementation and use of knowledge in educational organizations

due to the complex problems they show, as it is not easy to develop adaptive skills in them.

Currently conducting research projects in information science demand multidisciplinary task as it is in this case; phonetics, special education, computer science and psychology.

To offer computer science teachers and students resources for research and development of software, related to phonetics, speech recognition and aphasia.

The problematic identified should be resolved by the systems theory of management to interpret organizational behavior due to the complexity of the AT. This theory helps to the managers and teachers to understand the concepts: knowledge, adaptation, relationships and environment.

CONCLUSION

The element of therapy which had the greatest influence on children was the positive behavior, quickly identifying sounds and to a lesser extent the recognition of words. This is the area where more work is recommended.

Several special education teachers have accepted the implementation of the proposed program of AT. The viability depends on the approval of education authorities, as it is not only an economic resource issue, but it means also to prepare teachers for the acceptance of change and the use of this technology.

KEY TERMS AND DEFINITIONS

E

Aphasia: An impairment of language, affecting the production or comprehension of speech and the ability to read or write.

Center for Multiple Attention: Schools for students with disabilities to develop various skills known in México as CAM.

Consistency Matrix: A Chart to verify the logical coherency in a research method and to develop a tool for data collection.

Deaf: The person whose hearing is not functional for ordinary life.

Hypoacoustic: A person whose hearing, though poor, is functional with or without prostheses.

Methodological Consistency: Research method, which consists in relating the basic elements in a table to verify the logical relationship of the study.

Motivational Context: Cognitive affective factor present in every act of learning.

Digital Storytelling in Language Classes

Mehrak Rahimi

Shahid Rajaei Teacher Training University, Iran

INTRODUCTION

Storytelling is an effective and unique way of communication that takes the listeners into an imaginary world, motivates them to think about the happenings and phenomena and sometimes even induces them to do things (Handler-Miller, 2004). Storytelling makes connections between a storyteller and the audience (Smyth, 2005) and thus lets both express and share their emotions and thoughts.

Story is an old-fashioned human experience (McDrury & Alterio, 2003) and “a natural component of society and culture” (Frazel, 2011, p. 6). Stories are made, told, read, and listened to by people with different tastes and views (Jones, 2006) for transferring knowledge and/or sharing experience. The social value of storytelling and writing lies in the fact that stories can link past, present, and future generations (Chung, 2007) of micro and macro cultures and pave the way for the nation to preserve their cultural heritage. It is believed that as the food people consume makes their bodies, the stories they hear construct their minds (Wright, 2008) and form their viewpoints on the world and life.

Recent studies on human’s memory show that the brain saves the events in the form of scenarios (Schank, 1990) or chains of happenings. The human’s brain is story-oriented and experiences are kept like storyboards and thus are not very easily forgotten. This feature of brain and memory has inspired practitioners and educationist to take advantage of storytelling as a technique for training, teaching, and learning (Handler-Miller, 2004). Storytelling can improve teacher quality (McDrury & Alterio, 2003) and is an effective teaching tool that helps students understand intricate and

complex experiences and concepts (Sadik, 2008). Stories prepare learners for communication; make them literate; engage them in an entertaining way (Huffaker, 2004); help them learn language forms; and expand their vocabulary stock (Wang, Li, & Dai, 2008). It is empirically verified that stories can promote students’ problem solving skills (Radbakhsh, Mohammadifar, & Kianersi, 2013); increase their attention and motivation (Mostafazadeh, 2010); lower the physiological and emotional anxiety (Zarei, et al., 2013); and increase their self-esteem (Soltani, Arian, & Angoji, 2013) while making learning more joyful and less frustrating (Rahimi & Soleymani, 2015a).

Stories convey their message when they are told orally, written in words, or are drawn as images. The most primitive way of recording and transferring stories into the future was cave wall drawings. This mechanism of knowledge transferring was altered fundamentally by the invention of writing and then printing press. In the 21st century, technology and its varying forms have had a far reaching influence on the way stories are told, stored, and shared. Traditional forms of storytelling now have evolved into modern ways of storytelling called digital storytelling (Frazel, 2011), where stories are told by the combination of narration, music, images, texts, and movies. In other words, the audiences do not just listen to a story or read it, they have this opportunity to listen, read, watch, and enjoy the combination of different media in the environment of digital devices.

This type of storytelling has attracted the attention of researchers especially pedagogues to scrutinize its impact on learning different subjects. Significant characteristics of digital stories such as flexibility, universality, and interactivity have made them a practical and powerful technologi-

DOI: 10.4018/978-1-5225-2255-3.ch213

cal tool in instruction. In this way, listening to stories can grant the opportunity for students to enhance their engagement in problem solving and deep learning as well as working collaboratively in teams.

Although digital storytelling has been found to be a valuable technique of teaching, language teachers have shown some resistance to use it in their teaching due to certain reasons including

- A lack of confidence in their ability to tell stories or read storybooks aloud.
- A feeling that the language in storybooks was too difficult.
- A feeling that the content of storybooks was sometimes too childish.
- A lack of understanding about the true value of using storybooks.
- A lack of understanding of how to use storybooks and of time to prepare a plan of work (Ellis & Brewster, 2014, p. 6).

One way to overcome these resistances is providing teachers with required resources, giving them technical and pedagogical support to develop appropriate teaching materials, and providing them with other teachers' experiences (Ellis & Brewster, 2014, p. 6). To give more guidance to language teachers, this chapter deals with basic features of digital stories, the educational values of digital stories, and how they can be made and used in teaching. The chapter thus is organized in four sections dealing with theoretical framework of digital stories, the salient features of digital stories, educational values of digital storytelling, and the making of digital stories.

BACKGROUND

Joe Lambert, Bernajean Porter, and Dana Atchley are the pioneers and founders of digital storytelling (Frazel, 2011). The term *digital storytelling* (DST) was coined by Dana Atchley, who adapted and improved her personal stories through the use

of digital media (McLellan, 2006). Later, Lambert was astonished by the way people can easily, fast, and with a little price capture their stories using this technique (Robin, 2008). In 1994, the San Francisco Digital Media Center, which later became the Center for Digital Storytelling (CDS), was founded by Joe Lambert, Dana Atchley, and Nina Mullen. Since then, this center has been responsible for developing, training and helping individuals who are interested in creating digital stories and telling personal stories (Robin, 2008).

It is hard to give an exact definition of digital storytelling because it has been used in many different ways. Digital storytelling employs the art of storytelling and technological tools using graphics, images, music and sound mixed together with the creator's own voice (Porter, 2004). It is the act of merging unmoving images with a narrated soundtrack including both music and voice (Bull & Kajder, 2004). Lambert (2009) defines digital storytelling as sharing one's story through several medium of voice, imagery, music, text, sound, video and animation. Based on a five-part definition, digital stories should (Kittle, 2009):

- Include a compelling narration of a story;
- Provide a meaningful context for understanding the story being told;
- Use images to capture and/or expand upon emotions found in the narrative;
- Employ music and other sound effects to reinforce ideas;
- Invite thoughtful reflection from their audience(s) (p. 169).

Digital stories can be made by both students and teachers by narrating different types of stories from personal experiences to historical events or literary works. The stories can have different topics based on the creators' interests and needs (Gyabak & Godina, 2011). Digital stories can be made very easily with different types of movie maker software programs or online platforms.

The main underlying theoretical basis of digital stories is Cognitive Theory of Multimedia Learn-

ing (CTML) (Mayer, 2005). CTML basically focuses on understanding how learning takes place through cognitive processes such as selecting (transferring some incoming data to working memory for further processing), organizing (classifying images and words into pictorial and verbal models respectively in the working memory), and integrating (connecting the pictorial, verbal, and schemata activated from the long term memory).

CTML works based on the assumption that the working memory's storage capacity is limited and the instructional design should minimize working memory load to utilize the greater capacity of long-term memory. This is possible through eliminating the unrelated information and chunking the related information in the long-term memory schema (Renkl & Atkinson, 2003). Hence, the visual information processing channel might become overloaded when students process on-screen graphics and on-screen text at the same time (Mayer, 2001). Using narration can reduce the cognitive load in the visual channel by processing words in the verbal channel (Figure 1).

Another scientific theory that can be associated with digital storytelling is 'mediation'. Based on sociocultural theory "human forms of mental activity arise in the interactions we enter into with other members of our culture and with the specific experiences we have with the artifacts produced by our ancestors and by out contemporaries"

(Lantolf, 2000, p. 79). The process of mediation in second language learning involves "1. mediation by others in social interaction, 2. mediation by self through private speech, and 3. Mediation by artifacts (for example, tasks and technology) (Ellis, 2008, p. 270).

It is evident that computer-based multimedia can help students learn better than traditional classrooms (Bagui, 1998). Based on the theories mentioned, the success of multimedia in language learning can be attributed to three basic factors:

- The dual coding or using more than one code during the learning process (Najjar, 1996); as two media improve learning better than one (Mayer & Anderson, 1991).
- Presenting the information in a non-linear format (in a hypermedia format).
- Interactivity of multimedia in comparison with traditional methods and its flexible learning environment (Najjar, 1996).

Educational Value of Digital Storytelling

Some characteristics of digital storytelling such as flexibility, universality, and interactivity have made it a beneficial tool in learning and teaching (Park & Seo, 2009). Digital stories can engage students in problem solving (Kajder, 2004) and

Figure 1. Cognitive Theory of Multimedia Learning (CTML)
Mayer, 2005, p. 37.

deep learning (Pounsford, 2007). Further, they can make learners technologically competent (Ware, 2006) and increase their collaboration and group working (Di Blas, 2010). Digital stories can enhance learners' creativity (Park & Baek, 2009) and make them interested in learning (Tsou, Wang, & Tzeng, 2006). They utilize both teachers and students' imagination (Robin & Pierson, 2005) and enable teachers to integrate technologies and stories into the teaching program (Porter, 2006) more effectively. Digital stories can be applied in the classroom to motivate students (Coiro, 2003) and notify, teach or communicate with them (Robin, 2008) owing to its discontinuity, nonlinearity, and autonomy (Signes, 2008).

Digital stories provide students with authentic scenarios linked to their personal experiences and thus makes the content easier to be understood (Neo & Neo, 2010) while engaging both teachers and students actively in the class procedure (Dockter, Haug, & Lewis, 2010). Teachers have found multimedia-rich digital stories to be powerful learning tools for instruction across curricular subjects (Robin, 2008). It is believed that digital stories can develop five various skills consisting of (Robin, 2008):

- **Digital Literacy:** The ability to communicate with a community to discuss subjects and catch information.
- **Global Literacy:** The ability to read, respond, and interpret messages from a global view.
- **Technology Literacy:** The ability to apply computers and other technology.
- **Visual Literacy:** The ability to understand through visual images.
- **Information Literacy:** The ability to find and evaluate information.

It is also believed that using digital stories in the classroom has certain benefits such as (Frazel, 2011):

- Creating individualized digital stories as a class assignment.
- Engaging and motivating students to learn the content.
- Addressing the learning needs of K-12 students.
- Providing opportunities to apply emerging technologies as part of the students' learning.
- Supporting team teaching and learning across the curriculum.
- Providing an active instructional format and promoting group activities in the classroom.

Additionally, twelve unique characteristics of digital stories have been suggested by Schafer (2004) to have a vital role in learning and teaching including: interactivity, coherence, concreteness, involvement, cognitive effort, continuity, control, structure, vitality, spatiality, collaboration and immersion.

Digital devices are increasingly being used in education with the progress of technology. Some studies have been done on scrutinizing the value of digital stories in education in the last decade. The positive impact of using digital stories on literacy skills (Kajder, 2004), listening comprehension (Verdugo & Belmonte, 2007), understanding theoretical concepts (Coventry, 2008), learning of school subjects such as English, science, math, and social science (Sadik, 2008), creativity and cultural awareness (Benmayor, 2008), learning achievement, writing skill, verbal skills, critical thinking (Yuskel, Robin, & McNeil, 2011), learning motivation (Yang & Wu, 2012), reading comprehension and vocabulary learning (Chuang & Kue, 2013), literacy skills (Abdollahpour & Asadzadeh Maleki, 2012), listening comprehension (Soureshjani & Etemadim 2012), and listening anxiety (Rahimi & Soleymani, 2015a) is now evident.

How to Make Digital Stories

Making digital stories is not a difficult job, especially by the availability of lots of software programs made for producing movies and animation, both offline and online. Producing digital stories has two distinct parts: one part is related to language and content including the topic, difficulty level, and the length of the story; another part is related to technical and artistic aspects of making the multimedia file. Generally, seven elements have been identified by scholars in producing digital stories including (Lambert, 2010):

1. Point of view (what of the story) which shows the intention of the author of the story or the main point of it.
2. Dramatic question (why of the story) provokes the audience's inquisitiveness, will be answered by the end of the story and keeps the audience members' attention.
3. Emotional connection to the listener which involves the audience in the story or writing of the story.
4. Economy avoids overloading the viewer with excessive use of visuals and/or audio.
5. Pacing provides a rhythm to the story and copes with how slowly or quickly it moves.
6. The gift of voice (narration of the text) helps the audience understand the story through personalization of the narration.
7. The accompanying soundtrack (music) supports the story with appropriate music.

Digital stories can be made by a variety of media editing software including Movie Maker, iMovie, Photo Story, and Corel VideoStudio Pro (Skinner & Hagood, 2008). Digital stories can differ in length; but most stories generally last between two and five minutes. It is suggested that after minute 3, attention to the multimedia and thus comprehension declines (Rahimi & Soleymani, 2015b).

Generally speaking three stages are necessary in making digital stories: Preparation, production, and presentation.

Preparation stage is the stage before creating the story, where the audience and the way of presenting the story are determined. The story map for writing the script should be prepared here as well. In addition, the creator or the storyteller determines the type of final product (video or podcast) and how it will be presented to the audience (online or face to face). In the classroom situation, the teacher with the help of students decides about the theme of the stories and the type of audience. Then, they organize preliminary materials and plan for digital storytelling project/assignment. The teacher will decide at this point whether to have students work as individuals, in small groups, or as a whole class.

As a part of preparation, the teacher may choose to create an introductory digital story about the selected topic and have students brainstorm ways to find meaning, point of views, or emotional connections they had with the narrator. In this part the language teacher pays careful attention to the content of the story by considering the difficulty level of the story and the number of new words and grammatical points it has. One way to take these into account is calculating the readability of the story based on the available indices. The difficulty level of the story should have the features of 'the comprehensible input' and thus be in the range of students' language repertoire, or competence.

In *production stage*, the digital story file is produced by the teacher or students. Once all the resources and the storyboard are ready, students begin production phase. Students should be familiar with the media editing software to create multimedia stories. However, it is possible for the students to create an audio story, or a podcast using audio production software. The teacher acts as a mentor, and aids students with activities such as putting the slides in order or timing the slides. Music and sound effects may be employed. Most

of the required media can be found from different websites and programs. Enthusiastic students create much of their own media.

The prepared digital stories should be reviewed and assessed by other colleagues or peers before the files are going to be shared. Based on the provided feedback the file(s) would be edited. Any problematic content including words, and grammatical structures would be modified at this stage.

Presentation stage is the last but the most critical step among all in which prepared files will be used in the classroom or shared through the Internet (Frazel, 2011). For presentation, the digital story should be saved onto a file sharing website or written onto a CD or DVD.

There are numerous variations of this process and many genres of digital stories and digital story making applications are available (Frazel, 2011).

Digital Storytelling Teachers

In order to make digital stories the following steps should be followed by teachers:

Stage One

1. Selecting a topic for the story based on students' interest and needs.
2. Deciding on the purpose of the story. Is it going to inform, convince, provoke, or improve language skills?
3. Deciding on the point of view of the story.
4. Writing a script for the story.
5. If the story is taken from English literature, the text should undergo linguistic filters to make the text appropriate for the students based on their language proficiency level.

Stage Two

1. Searching for image resources for the story including pictures, drawings, or photographs.
2. Finding music resources and sound effects.
3. Importing images into a media editing program (e.g. Movie Maker).

4. Modifying images and/or image order, if necessary.
5. Mixing the narration and images and creating necessary special effects and graphics using the facilities of the software.
6. Saving the digital story file onto a DVD (MP4) to be watched and listened to by technological devices (such as cell phones, tablets, or laptops).

Stage Three

1. Reviewing of the digital story by colleagues.
2. Using the received feedback to improve and revise the story.
3. Finalizing and preparing the digital story to be performed in the classroom (Frazel, 2011).

Teachers can use different types of questions for developing critical thinking activities to accompany digital storytelling projects. These questions are useful for getting students to think about different parts of the story and improve both their general and language knowledge. Followings are sample questions that can be asked

- What are other possible ways to tell this story?
- What do we expect the audience to tell us at the end of this story?
- What is the role of music in this story?
- What additional information might the audience need to understand the story better?
- What happens if the music and special effects (e.g., graphics) are removed?

Language teachers can use digital stories in teaching four language skills, that is listening, speaking, reading, and writing. The teachers can use this invaluable teaching content to arise students' interest to go through a language task or work on digital stories as independent language tasks. Different types of exercises and activities

can be designed to be done during listening and watching the files or in the phase after it.

Digital Storytelling Students

Morra (2014) has given the detailed description of how teachers and students can make digital stories together in the classroom by specifying an 8-step cycle (Figure 2).

Start with an Idea

Like all stories, digital stories should begin with an idea such as student's questions or topic of a text or lesson. When the basic ideas/themes are discussed and agreed upon, the teacher or students should convert them to concrete materials such as a draft, an outline or a concept map.

Research/Explore/Learn

Students should gather information about the topic they have selected. Different resources are recommended to find more information about the topic; the Internet seems to be the more useful one.

However, atlases, encyclopedias, and periodicals are recommended to be searched as more authentic and trustworthy resources.

Write/Script

Based on the general theme and the specific information found, the students start writing the script. This is the first draft of the story. The script can be reviewed by peers and the teacher for corrections and improvement. So it is possible that different drafts are written and re-written before the final script is produced. It is noteworthy that script writing of the story should follow the process of writing including drafting, revising, editing, and producing the final product based on the feedback received. As a result digital stories are suitable language tasks for collaborative writing in language classes.

Storyboard/Plan

The writing will be converted into storyboards by the help of which students prepare a *graphic*

*Figure 2. The 8-step cycle of making digital stories
Morra, 2014.*

representation of the script with specified characters and sequences of events.

Storyboards can be made on paper or using media producer software (Figure 3).

As the storyboard is the basis of the story, it is recommended that students spend quality time on this stage to produce storyboards that are understandable and manageable to be made. Otherwise they may face serious problems in producing the multimedia file.

Gather and Create Images, Audio, and Video

To change the storyboard into a real story, images, audios, and videos are required. Students should follow the steps of the storyboard carefully and find the necessary media to make the digital story.

Put It All Together

At this stage students put everything together based on the storyboard in the technology environment. They have to use the affordances of the media producing software to make the digital story as attractive as possible. In other words, the pictures, narration, and the background music will be mixed while special digital effects are added in the environment of the software. This stage needs much of taste and artistry from the side of students.

Share

When the story is made, it should be shared with the audience. This can be done online using the available platforms or offline as digital video files copied on DVDs.

Reflection and Feedback

At the end, the students reflect on their own work and give feedback to the works of others. Online or in-class sessions can be used to help students get feedback and opinion about their made stories (Kajder et al, 2005). In this phase students can do lots of activities including discussions and debates and writing critical paragraphs.

SOLUTIONS AND RECOMMENDATIONS

This chapter aimed at making language teachers familiar with a handy technological artifact that can be easily made both by teachers and students and used in language classes. Digital stories have been reported to be valuable instructional materials in mainstream education, however, their miraculous role in promoting language learning is just being revealed.

Figure 3. A simple storyboard
Bird, 2011

Digital stories can be used in teaching and practicing almost any type of language activity including macro language skills (listening, speaking, reading, and writing) and micro skills (pronunciation, vocabulary, and grammar). As multimedia files, they can improve the capacity of working and short term memory and make things being remembered longer. As collaborative tasks, they let language learners participate in making stories and then acquire new points by cooperation and collaboration. Further, as they are symbolic artifacts, they can enhance the cognitive process and impact the way students think and process information. One possible benefit of human/technology interaction “is *transfer* of the partnered skill to the individual such that a particular mental operation that entails technology is mastered to a greater degree as a result of the partnership” (Lantofl, 2000, p. 93).

It is noteworthy to mention that without necessary skills and knowledge base of making digital stories their effect in language classes may be spoiled, as a part of teacher Technological Pedagogical and Content Knowledge (TPACK) is being able to integrate technology in instruction based on sound pedagogical theories and practices.

FUTURE RESEARCH DIRECTIONS

This study investigated the educational values of digital stories in mainstream education in general and teaching English as a foreign language in particular. It also familiarized language teachers with how to make and use digital stories in language classes.

Language educationists and teachers are urged to do empirical studies on the theoretical guidelines this chapter or similar works offer to verify the value of digital stories in language classes. This may include studies done to compare the effects of digital story in teaching receptive and productive language skills as well as the impact of digital storytelling teachers vs. digital storytelling students.

Comparative quantitative and qualitative studies on the way teachers/students with different personal characteristics make and use digital stories in teaching and learning English are required to be examined. The mediating role of nationality and the context of teaching and learning can also be investigated.

Other types of multimedia contents such as multimedia stories and posters are also required to be introduced to teachers and their effects be examined empirically.

CONCLUSION

This chapter presents some guidelines on what digital stories are and how they can be made to be used in teaching, particularly in language classes. The chapter opens with an introduction on the key role of literature and especially stories in peoples’ life and education. It further goes on with probing into the value of digital storytelling as an innovative technique in pedagogy. The chapter ends with listing educational values of digital stories and how teachers can make and use them in their teaching.

KEY TERMS AND DEFINITIONS

Collaborative Storytelling: A kind of digital storytelling by which groups of students work on certain themes to produce and share their stories with others by collaborative technologies such as online story making platforms.

Digital Storytelling: Sharing one's story through several medium of voice, imagery, music, text, sound, video and animation using technological tools.

Movie Makers: Software programs that let the users combine pictures, sound, music, and movie to make multimedia content.

Multimedia: The combination of several media (sound, image, graphics, movies, music) to present content.

Multimedia Cognitive Theory of Learning (MCTL): The underlying theoretical basis of digital storytelling that deals with how learning takes place through cognitive processes such as selecting, organizing, and integrating.

Multimedia Learning: The kind of learning that focuses on how people learn more deeply from words and graphics than from words alone.

Storytelling: Narrating sequences of events in an artistic manner for a group of audience orally or in written words.

Teacher-Made Digital Stories: Digital stories that are made by teachers based on the objectives of the lesson to teach a certain point/objective.

Distance Teaching and Learning Platforms

E

Linda D. Grooms

Regent University, USA

INTRODUCTION

The knowledge explosion, the increased complexity of human life, and the ubiquitous, 24/7 nature of technology coupled with the globalization of the marketplace herald the need to embrace the most effective methods and formats of teaching and learning. Currently providing powerful educational opportunities, the science and technology of distance learning continues to multiply at unprecedented rates. Where historically traveling from village to village verbally disseminating knowledge was the only process of training those at a distance, today's learners eagerly embrace the rapidly expanding web-based delivery systems of the 21st century, which offer a plethora of educational alternatives. So with this rapidly changing distance educational landscape, one must question, what exactly is distance teaching and learning, how has it evolved, and what is its future?

BACKGROUND

In very simplistic terms, distance learning is just that--learning that occurs at a distance (Rumble & Keegan, 1982; Shale, 1990; Shale & Garrison, 1990) or that which is characterized by a separation in geographical proximity and/or time (Holmberg, 1974, 1977, 1981; Kaye, 1981, 1982, 1988; Keegan, 1980; McIsaac & Gunawardena, 1996; Moore, 1973, 1980, 1983, 1989a, 1989b, 1990; Ohler, 1991; Sewart, 1981; Wedemeyer, 1971). In his 1986 theory of transactional distance, Moore (Moore & Kearsley, 1996) defined distance not only in terms of place and time but also in terms of structure and dialogue between the learner and the instructor. In this theory, distance

becomes more pedagogical than geographical. As structure increases, so does distance. As dialogue increases, distance declines thus establishing the foundational role interaction plays in the distance learning environment. Saba (1998) furthered this concept concluding,

... the dynamic and systemic study of distance education has made 'distance' irrelevant, and has made mediated communication and construction of knowledge the relevant issue So the proper question is not whether distance education is comparable to a hypothetical 'traditional,' or face-to-face instruction, but if there is enough interaction between the learner and the instructor for the learner to find meaning and develop new knowledge. (p. 5)

To facilitate greater interaction in the geographically and/or organizationally dispersed distance environment, today the convergence or fusion of technologies enable individuals to overcome the barrier of separation, affording institutional and learner opportunity to transcend intra- and inter-organizational boundaries, time, and even culture. By definition, the paradigm of distance, online, or e-learning revolutionizes the traditional environment; however, even with this change, learning, which involves some manner of interaction with content, instructor, and/or peers, remains at the core of the educational process.

Although imperative in both environments, research shows these three types of interaction to be the hub of the ongoing traditional versus distance argument. Traditionalists often fear that with anything other than face-to-face instruction, interaction somehow will decrease thus making learning less effective, when in reality, numerous

DOI: 10.4018/978-1-5225-2255-3.ch214

studies have revealed no significant difference in the learning outcomes between traditional and distance courses (Russell, 1999). In fact, distance courses have been found to “match conventional on-campus, face-to-face courses in both rigor and quality of outcomes” (Pittman, 1997, p. 42). Despite these findings, critics still abound.

Two distinguishing characteristics of the non-traditional environment--individualized learning and flexibility--often arouse suspicion and caution among traditionalists (Grooms, 2000). Many are convinced that with any form of study outside the confines of the typical brick and mortar, “every vestige of intellectual rigor [will] disappear into oblivion.... [These skeptics interpret] individualized learning as individualized isolation, especially from faculty, and they look on flexibility as no more than a synonym for escape from regulation and responsibility” (Gould, 1972, p. 9).

In contrast, with their introduction of Equivalency Theory, Simonson, Schlosser, and Hanson (1999) accentuated the concept of equivalency as “central to the widespread acceptance of distance education” (p. 72) thus supporting Keegan’s (1989) call for parity in quality, quantity, and status. Further, recognizing the need to bring integrity and prestige to the field, Shale and Garrison (1990) suggested building a framework based not on isolation but upon interdependence, which would imply that distance learning would merely become an alternative method for delivering traditional content with the context dictating the type of interaction required. So how did we get to where we are now?

MAIN FOCUS OF THE ARTICLE

Distance Learning Evolution

As previously mentioned, distance learning has been with us in one form or another virtually since the creation of time. For years, itinerant teachers traveled from village to village verbally disseminating information to those hungry for knowledge;

however, the invention of Guttenberg’s printing press in 1440, made possible serious distribution of learning to larger numbers of people.

Capitalizing on this broader use of print media, correspondence study became a popular form of distance education, the first record of which was in 1728 when Caleb Philipps’ advertised the introduction of shorthand (Battenberg as cited in Baath, 1980 & Holmberg, 1986). Often conjuring thoughts of isolation and autonomy, this record of instruction mirrored those images. In fact, in this account there was no mention of interaction of any type other than what was inherent with the content.

Over a hundred years later in his 1833 Swedish advertisement, although not directly stated, Meuller’s offer to study composition seems to be the first to imply some form of exchange between the student and teacher. More definitively, in 1840, the most acknowledged root of distance learning explicitly employing learner-instructor interaction began in the United Kingdom. Using passages from the Bible, Isaac Pitman taught shorthand (Baath, 1980; Holmberg, 1974; Kaye, 1988; Rumble, 1986), yet this time, once learners transcribed these passages, they were returned for correspondence with the teacher via the penny post, thus some called it postal teaching (Dewal, 1988).

As evidenced in these early days of pure correspondence education, any offered guidance transpired through some form of dispatched communication such as the mail (Wedemeyer, 1971) and student contact, even with the instructor, was not necessarily encouraged. This is clearly seen in Keegan’s (1980) classic article, *On Defining Distance Education*, where he documented that in its strictest sense, pure correspondence study advocates specified that “students enrol [sic] with them because they ‘want to be left alone’” (p. 31). Directly challenging this belief, Holmberg (1982) later advocated that “any post-graduate distance study must have a truly communicative character if more is meant than merely providing reading lists and odd comments on students’ work” (p. 259).

While print remained the primary mode of distance learning until the 1920s and 30s, the introduction of radio broadcasts soon followed with television and satellite delivery systems initiating the labor pains for the birth of the current online technological revolution. Prior to the advent of the World Wide Web (WWW) in the early 1990s, interaction continued to transpire primarily between the learner and content with occasional interaction between the learner and the instructor through such means as telephone and videoconferencing.

As the distance learning landscape continued to evolve, learner-instructor interaction became increasingly important, thus catapulting the first of two significant paradigm shifts. While some (Daniel & Marquis, 1979) were accentuating the importance of getting the right independence-interaction mixture, others heralded the positive impact (e.g. Cookson, 1989; Robinson, 1981) and, even more so, the critical nature of the tension between the role of technology and type of educational process with its accompanying interaction in the distance learning environment (e.g. Bocarnea, Grooms, & Reid-Martinez, 2006; Grooms, 2000, 2003; Grooms & Reid-Martinez, 2011, 2012, 2013).

The Current State of Affairs

To be embraced, any new mode or method of education such as distance learning with its multiple technological changes must do more than merely emulate the status quo of traditional education. The virtual environment of the 21st century claims to do just that. While offering flexibility from traditional geographical proximity and time constraints (Barnes & Greller, 1994; Harasim, 1990; Hiltz & Johnson, 1990; Kaye, 1989; Moore, 1983), computer-mediated communication (CMC) (Harasim, 1993; Kaye, 1989; McIsaac & Gunawardena, 1996) and other information and communication technology (ICT) serve as excellent participation equalizers or what

Szecszy (2011) refers to as “leveling devices.” These unprecedented technological advances increasingly blur the line between traditional face-to-face learning and that which occurs at a distance.

While multiple studies have indicated there is no significant difference between distance and traditional learning effectiveness, the geographical dispersion of people, shifting market conditions, and rapid technological changes continue to compel transformation in the way we do business both in the marketplace and in the halls of academe. Promising to deliver increased access, quality, and efficiency of learning in an ever-growing competitive market (Benoit, Benoit, Milyo, & Hansen, 2006), as it moved online, the technology of higher education altered both teaching and learning (Kapitzke, 2000) and instructor and student roles (Stadtlander, 1998). With this in mind and regardless if its now considered online, e- or m-, learning is now mediated through synchronous (interactive/real time) or asynchronous (delayed interaction) means and the most critical consideration continues to remain in aligning the task, the delivery method, and the delivery format.

Distance Learning Delivery Methods

Almost 150 years following the advent of postal teaching and the first record of any form of learner-instructor interaction, Linda Harasim (1989), a pioneer in the online classroom, clearly differentiated three delivery methods that she believed distinguished traditional, distance, and online education: *one-to-many*, as in the traditional lecture method when one instructor addresses many students; *one-to-one*, as in the tutorial method; and *many-to-many*, a collaborative process with students learning from each other, with or without an instructor. In the first method, learners are mere passive recipients of knowledge and information, whereas in the latter two, they are actively involved in the learning process. A clear shift in the role of the instructor transpired: from information dispenser to one who facilitates an environment

where knowledge “emerges from active dialogue among those who seek to understand and apply concepts and techniques” (Hiltz, 1990, p. 135).

Although the traditional face-to-face environment is time-place dependent, it allows for the implementation of all three delivery methods contingent upon the instructional task. In contrast, the distance and online environments are time-place independent and mediated, facilitating flexibility and reflective response; however, in like manner they also align method with context. When appropriate, distance learning uses the *one-to-one* (e.g., print media, programmed instruction, adaptive educational hypermedia, or even 3D and immersive virtual worlds) or *one-to-many* (e.g., audio teaching, streaming video, podcasting, or

even videologging such as YouTube) methods, while online classes additionally employ the *many-to-many* concept, which forces the second paradigm shift: the need for peer interaction which often uses such platforms as chat rooms, instant messaging, or one of the many web conferencing options.

Distance Learning Delivery Formats

Distance learning formats typically corral into four arenas: print, audio, video, or digital (see Table 1) with all serving as viable options. Apart from media or technology differences, communication within these formats can either be one-way with the learner taking a passive role or two-way with

Table 1. Distance learning delivery formats

Media	Passive One-Way	Interactive Two-Way	
		Asynchronous Delayed	Synchronous Real Time
Print	• Syllabi • Texts • Instructor notes • Study guides • Workbooks • Fax		
Audio	• Radio • Audiotape • CD Rom • Voicemail		• Telephone • Audio Conferencing
Video	• Videotapes • DVD • Film • Cable, Broadcast, and Digital Television (one-way audio and video)		Satellite Videoconferencing (two-way audio and one-way video)
Digital	• CAI (computer assisted instruction) – using the computer as a self-contained teaching machine • Webcasts • Streaming Video • Podcasting & its varied forms (e.g. Vodcasting & Phoningcasting) • Some forms of blogging such as moblogging, linklogging, photologging, edublogging, and videologging such as YouTube	• CMI (computer-mediated instruction) • E-mail • Texting • Bulletin Boards (Threaded Discussions; Newsgroups) • Listservs • Wikis • Web-based instruction (e.g., Blackboard) • Cloud Technology (e.g., Google Apps) • Open Source Learning Platforms (e.g., Moodle) • Social Networking (e.g., Facebook, LinkedIn, and Google+) • Other forms of blogging and many of its variations including microblogging (e.g., Twitter, Tumblr, and SnapChat)	• Web Conferencing (e.g., Webinars, Google Hangouts, Blackboard Collaborate, and GotoMeeting) • Chat Rooms • Instant Messaging • Shared Whiteboards • Interactive Optical Sensory Technology • 3D and Immersive Virtual Worlds • Adaptive educational hypermedia

the learner interacting with either the instructor or peers.

Whether using syllabi, texts, instructor notes, or other forms of print, today this medium still remains a significant component in distance learning. In addition, where telephones, audio conferencing, and video technology augmented print in the latter part of the 20th century, today the exponential proliferation of the Internet has provided a plethora of independent and collaborative learning opportunities, both synchronous and asynchronous. Regardless of the format, researchers (Beetham & Sharpe, 2007; Rourke & Coleman, 2011) caution that rather than technology driving pedagogy, pedagogy should drive technology with the ultimate goal always of learning.

Most recently with the plethora of multiple media at hand, many educational institutions have turned to massive open online courses (MOOCs), while others have employed a blended or hybrid learning approach combining some form of the traditional with the digital. Osguthorpe and Graham (2003) summarized the latter approach very well.

Those who use blended approaches base their pedagogy on the assumption that there are inherent benefits in face-to-face interaction (both among learners and between learner and instructor) as well as understanding that there are some inherent advantages to using online methods in their teaching. Thus, the aim of those using blended learning approaches is to find a harmonious balance between online access to knowledge and face-to-face interaction. The balance ... will vary for every course [based upon the] instructional goals, student characteristics, instructor background, and online resources ... No two courses will be exactly the same [The goal] is to ensure that the blend involves the strengths of each type of learning environment and none of the weaknesses. (p. 228)

Citing three typical reasons for using a blended approach--more effective pedagogy, increased convenience and access, and increased cost ef-

fectiveness (Graham, Allen, & Ure, 2005)--it is easy to see why progressively more institutions are implementing such a format.

Further blurring the line between traditional and distance learning, the blending and convergence of technologies continue to increase the fluidity and ubiquity of education. Today with the tap or swipe of a finger, learners have virtually instant access to a plethora of information via the Internet, which Klinger and Coffman (2011) claim provides a transformational highway for distance learning. Given the mobility of netbooks, smartphones, and tablets, geographical proximity becomes a non-issue as learners are no longer bound by context and can learn anytime and anywhere with social media producing an ecosystem ripe for interaction. Through time, the mobility of distance learning has remained constant; however, the delivery format has opened virtual horizons far beyond traveling from village to village. Foreshadowing this technological explosion, futurists McCain and Jukes (2001) projected that "at a certain point, the boundaries between reality and virtual reality will collapse because of the increased sophistication and transparency of these powerful, fused technologies" (p. 60). With the introduction of such things as cloud computing, adaptive educational hypermedia, interactive optical sensory technology, and three-dimensional virtual and immersive learning environments, that day has already arrived. So, where do we go from here?

FUTURE RESEARCH DIRECTIONS

The future of distance learning will continue to reflect the exponentially growing technological advances. In an April 1965 *Electronics* magazine article, Gordon Moore, cofounder and Chairman Emeritus of Intel, the world's largest silicon chip manufacturing company, predicted that the number of transistors on an integrated circuit would double every 12-18 months. While in 1975, he amended this timeframe to roughly every 24 months, it has been accurate in excess of one half century. At

present, what has become known as Moore's Law shows no signs of slowing down; although, in a 2000 interview with *Time* magazine, Moore did acknowledge that at some point in the next two or three generations, this growth would perhaps slow down to doubling every five years.

Exploring other technological alternatives, since the late 1950s some "wondered whether a better approach to miniaturization might be to 'grow' single molecules that functioned as electronic circuits or components. [They believed] that such molecules might be faster and smaller [than the traditional silicon chip] ... and they might also be easier to make" (Kelly & Mody, 2015, 8). While this movement has waxed and waned over the years, in 2010, researchers from Japan and Michigan Technological University claimed they had succeeded in building a molecular computer that could "replicate the inner mechanisms of the human brain, repairing itself and mimicking the massive parallelism that allows our brains to process information like no silicon-based computer can" (Borghino, 2010, 1). Four years later, Sebastian (2014) unveiled that IBM scientists had created "what some have claimed is the most advanced neuromorphic (brain-like) computer chip to date" (1).

Even with such remarkable advancements, we are quite a distance from reaching the apex of technological discovery, which history reveals directly affects distance teaching and learning. In reflection, these new discoveries "may very well prove the long-term solution to validate Moore's law well into the next century" (Borghino, 2010, p.2).

CONCLUSION

Whether one views distance as geographical or pedagogical, as the above suggests, the technological explosion of the 21st century provides unprecedented opportunity to render distance virtually irrelevant. If Moore's law holds fast and technology continues to double every 18-

24 months, the exponential growth of distance learning will continue to catapult educators into uncharted territory. The question remains, will there still be a place for the staunch traditionalist or will education continue to be so radically transformed that traditional education is hardly recognizable. Regardless of the medium (print, audio, video, or digital), method (one-to-many, one-to-one, or many-to-many), format (passive or interactive), or even device (PC, smartphone, tablet, or watch), interactive learning continues to remain at the core of the distance educational process.

Negroponte (1995) poignantly prophesied, "Distance means less and less in the digital world. In fact, an Internet user is utterly oblivious to it. On the Internet, distance often seems to function in reverse" (p. 178). Supporting this prediction, science and technology have triggered physical distance to become truly irrelevant. So, what does the future hold? Where *will* distance learning be in 5, 10, or even 20 years from now? Some would postulate that we are limited only by our imaginations.

KEY TERMS AND DEFINITIONS

Cloud Computing: Technologies that facilitate the sharing of digital files over the Internet.

Correspondence Learning: A form of distance learning using dispatched or one-way communication.

E-Learning: Learning that occurs electronically.

Equivalency: Distance learning that possesses equality with learning experienced in the face-to-face venue.

Face-to-Face Learning: Learning that is time-place dependent.

mLearning: Learning that occurs through the use of mobile technology.

Optical Sensory Technology: Technology that provides the ability to track user input within an augmented or virtual reality.

Three-Dimensional Virtual Learning: A computer-based simulated environment.

Time-Place Dependent: Education that transpires in the same location at the same time.

Time-Place Independent: Learning that does not rely on geographical proximity or time.

Traditional Study: Face-to-face learning.

INTRODUCTION

Mobile learning allows learners to construct their own learning experience (Bandalaria, 2007). This form of learning empowers students to develop their own skills and knowledge (Sharples, Taylor & Vavoula, 2007). Students, through the use of mobile learning, may create opportunities to learn anytime and anywhere (Martin & Ertzberger,

2013; Sanchez, Mendoza, & Salinas, 2009) and can connect that learning experience to real life situations. Recently, games have been integrated in mobile platforms. Educational technology developers combined the entertaining components of games with educational contents in order to develop games for pedagogical purposes.

However, the existing threads of discussion on serious game usability do not provide evidence as

to which of the usability features of a mobile game can influence student learning. This chapter aims to address this issue. A serious game in disaster response was developed and utilized by first-year students. The goal of this paper is to find answers to the following questions:

1. What is the knowledge of the disaster response participants before and after playing the game?
2. What is the learning gain of the students after playing the game?
3. What are the perceptions of the participants in the usability of the game in terms of content, ease of use, usefulness, and aesthetics?
4. Is there a significant difference between the knowledge of students on disaster response before and after playing the game?
5. Do the usability factors, singly or in combination, influence the knowledge of the participants in natural disaster response?

BACKGROUND

Mobile games can be utilized to channel information and learning. Games with educational content may engage people to play and learn at the same time (Muratet, Torguet, Jessel, & Viallet, 2009). Studies have documented the positive results of mobile games as educational tools. Batson & Feinberg (2006) showed that students who used educational games had a positive learning experience. Mobile educational games also improve the motivation of students to learn and to have positive attitudes towards learning (Tuzun, Yilmaz-Soylu, Karakus, Inal, & Kizilkaya, 2009; Salter, Pittaway, Swabey, Capstick, & Douglas, 2012). Chow, Woodford & Maes (2011) also revealed that the use of mobile educational games improved students' retention, critical thinking skills, and understanding of the content of an introductory statistics course (Chow et al., 2011). Moreover, it was proven that these educational materials can improve learners' problem solving

skills and can promote collaboration among them (Sanchez & Olivares 2011). Recently, Connolly, Boyle, MacArthur, Hainey, & Boyle (2012) summarized the results of 129 studies that investigated the impacts and outcomes of serious games on learning and students' classroom engagement. The researchers consistently found that playing serious games were associated to knowledge acquisition, content understanding, and affective and motivational outcomes.

Learning of students could also be measured in terms of learning gain. Learning gain is the measurement of performance in a test as indicated by the percentage points a student can gain from the first/previous test to the second/recent test (Colt, Davoudi, Murgu, & Rohani, 2011; Steif & Dollár, 2009). Rodrigo et al. (2013) utilized this measure to show that learning gains could be influenced by the ability of the students to solve problems. Bringula, Alvarez, Evangelista, & So (in press) used this measure to determine the impact of a mobile learning software on the mathematics performance of students. They found out that after using the mobile learning software, students increased their mathematics performance by 41%.

Various design models and guidelines were proposed in an attempt to guide educational game developers to develop serious games (e.g., Billi et al., 2010; Bringula, Alcid, Bandril, De Guzman, & Lopez, 2014). The goal of these models and guidelines is to balance the entertaining and educational components of the mobile game (Kreutzer, Marks, & Bowers, 2015). Usability of mobile games was explored in an attempt to warrant that the end product will be functional and playable (Olsen, Procci, & Bowers, 2011; Warren, Jons, & Lin, 2011). In an educational point of view, the purpose of the exploration of serious game usability is to ensure knowledge transfer (Kreutzer, Marks, & Bowers, 2015).

There is no universal definition of usability (Sindhuja & Dastidar, 2009). This is because usability is dependent on the content and nature of the systems being investigated. In mobile games

designed for educational purposes (that is, serious games), the usual metrics of usability—efficiency, effectiveness, and user satisfaction—may not be the appropriate criteria for a usable mobile game (Thomas, Schott, & Kambouri, 2003). Researchers suggested that educational game developers must balance learning component of games while maintaining the fun in the games (Thomas et al., 2003; Ibrahim, Vela, Rodriguez, Sanchez, & Zea, 2012). The content of the game can focus on the knowledge or skills that are intended to be inculcated or transferred (Thomas et al., 2003). Derakhshan (2009) showed that content was an important feature of a mobile learning environment. Kutluk and Gülmez (2014) disclosed that good organization and easy to navigate content were desirable characteristics of mobile learning environment. Shchiglik, Barnes, Scornavacca (2016) showed that the game content quality should be accurate, relevant, and easy to understand. Assuring the quality of game content can attract and motivate students to learn (Alqahtani & Mohammad, 2015).

The game must educate the users while they have fun playing the game. The game must be simple and enjoyable so that it captivates the imagination of the player (Ibrahim et al., 2012). Davis (1989) defined ease of use as a system quality factor which is related to user-friendliness of application design. In other words, ease of use is equated to the effort exerted in using a technology (Bringula, 2016). Tan, Ooi, Sim, & Phusavat (2012) showed that ease of use can affect intention to use mobile learning. Hence, ease of use influences the attitudes and behaviour of people towards the technology (Abu-al-Aish & Love, 2013; Alqahtani & Mohammad, 2015). In the context of mobile games, developers must ensure that the independent components of a game are easy to use (Olsen et al., 2011). In turn, learners may continue to use the game (Alqahtani & Mohammad, 2015). In a recent study, Shchiglik et al. (2016) showed that ease of use of games can be measured in terms of the following — easy to use, easy to learn and

operate, users know what to do, easy to navigate, easy to find things in the game.

The usefulness of the game is anchored to its game objective. The clarity of game objective is achieved when a player can explain the game (Bringula et al., 2014; Ibrahim et al., 2012). If learners can state the purpose of the game, they have an idea of its usefulness. The learners' perception of the usefulness of the game can influence their intention to use the game (Tan et al., 2012). Therefore, perceived usefulness is the expectation of users towards a new technology as well as the view that it would bring satisfaction and enhanced performance. Chittaro & Sioni (2015) provided evidence that a game in disaster response must contain useful recommendations in terms of safety, evacuation, and injury reduction.

Lastly, aesthetics is the most discussed factor of usability. In game design, aesthetics is the overall quality of visual design (Bringula et al., 2014). Game objects, text layout, buttons, graphics, and colors constitute the visual design of the game. Gamers are more particular in this aspect than the rest of other game design considerations. This is because the environment in mobile devices is different from the personal computers. In another study, Alqahtani & Mohammad (2015) included the adaptability of the application to the screen size of mobile devices, suitability of the design in landscape and portrait modes, and contentment with the design of the application as items of aesthetics. The findings of Shchiglik et al. (2016) are consistent to that of Alqahtani and Mohammad (2015).

However, it is still unclear which usability design factors may influence student learning. Current studies focus on the usability of serious games. Absent in the literature is the evidence as to whether these game usability features could influence user learning. The main focus of this article is to determine if game usability design features could influence learning. It is hypothesized that usability factors, singly or in combination, do not influence the knowledge of the participants in natural disaster response

THE EXPERIMENT AND MEASUREMENT OF LEARNING

A one-group pretest-posttest experimental design (Figure 1) was conducted by the researchers to address the main focus of the chapter. The study was conducted at the National University, Manila. Ninety-eight participants (34 female, 64 male, average age is 17.7 years old) have utilized a mobile android-based game named H.E.A.T. on disaster response (Figure 2). The participants used the game during their laboratory sessions for three consecutive days. The laboratory session lasted for one hour. This is the intervention period (denoted by *X*). A day before the intervention period, a pretest (denoted by *O*) was conducted to determine the prior knowledge of the participants on how to respond during a disaster. A day after the intervention period, a posttest (denoted by *O*) was administered. The experiment ran for five consecutive days. Each test contained 20 items.

THE USABILITY GAME DESIGN CRITERIA

The usability game design criteria were pretested to ensure its reliability and validity. Students from the University of the East assessed the software. It contained four dimensions which consisted of content, ease of use, usefulness, and aesthetics. Content was composed of three items. The first item refers to the completeness of the game. It measured the scope of the game in terms of different forms of natural calamities. The reliability of the game content is the third item of this dimension.

Ease of use was composed of six items. It evaluated if it may be easy to use the game controls and determined if all controls are functional. Learners must also feel that the game is easy to play. They must not be confused or lost when playing the game. They can also evaluate the game in terms of how easy it is to move from one game screen to another. The last item of this criterion asked the learners to rate the overall ease of using the game.

Usefulness, which is composed of four items, intended to measure the perceived educational value of the game in terms of disaster response. It

Figure 1. One-group pretest-posttest design

<i>O</i>	<i>X</i>	<i>O</i>
Knowledge on disaster response before using the game (pretest)	Use of the mobile game on disaster response (three days)	Knowledge on disaster response after using the game (posttest)

Figure 2. The game utilized in the study

determined the perceptions of the learners in terms of how much they learned from the game. Moreover, it contains an item that examined whether the game gave useful information and tips. The last criterion was aesthetics. It consisted of seven items relating to attractiveness of screen layout, comfort when playing games, appropriateness of colors, legibility of font sizes and font styles, and overall attractiveness of the game.

RESULTS

It was found that the pretest score on storm had the lowest percentage at 50% while pretest score in earthquake had the highest percentage at 77%. After the intervention period, all test scores were higher. Posttest scores in earthquake, flood, and tsunami are all 81%. The overall mean also went up from 59% to 74%. Students had the most learning gain (l.g.) in terms of knowledge in flood (l.g. = 60%). Overall, the learning gain is 35%.

The same sample *t*-test revealed that there is a significant difference on the posttest and pretest scores in fire ($d = 0.66$, $t(97) = 4.55$),

flood ($d = 0.83$, $t(97) = 8.40$), tsunami ($d = 0.60$, $t(97) = 5.20$), and volcanic eruption ($d = 0.56$, $t(97) = 4.80$). All results are significant at 0.05 level of confidence. Hence, the results are unlikely to have arisen from sampling error. On the other hand, the differences on the scores are not significant in storm ($d = 0.06$, $t(97) = 0.46$, $p = 0.644$) and earthquake ($d = 0.16$, $t(97) = 1.50$, $p = 0.138$).

Usefulness had the highest mean rating of 4.18 (s.d. = 0.75), while aesthetics had the lowest mean rating of 3.05 (s.d. = 0.86). Respondents agreed that the content of the game (mean = 3.92, s.d. = 0.69) is acceptable and useful (mean = 4.18, s.d. = 0.75). The standard deviations of all criteria showed that the responses are not dispersed.

The responses in the open-ended questions were analyzed by taking keywords. The keywords were then grouped to determine the themes. The results are shown in Table 1. It was disclosed that the five themes emerged. Three out of the five themes are covered in the current study. Respondents commented that the game is easy to use and play. Also, the controls of the game need to be improved. In term of aesthetics, 27 respondents

Table 1. Results of open-ended questions

Ease of Use • easy to use and play (2 times mentioned) • controls need to be improved (4 times mentioned)
Usefulness • respondents learned a lot of lessons about disasters (6 times mentioned) • helped provide knowledge on what to do during calamities (8 times mentioned) • gave tips on what to do during calamity • very informative (6 times mentioned) • good game for students (2 times mentioned) • gave awareness about disasters • useful (2 times mentioned)
Aesthetics • graphics needs to be improved (27 times mentioned)
Fun • very enjoyable to play (2 times mentioned) • fun (3 times mentioned) • happy • boring
Effectiveness • tasks proved a bit time-limited • walking of character is slow (14 times mentioned) • game occupied a large memory (3 times mentioned)

advised that the graphics of the game need to be upgraded. Twenty-six respondents agreed that the game is informative and useful. The fun component of the game is included as six participants expressed enjoyment with the game while one participant expressed otherwise. Contrary to the study of Thomas et al. (2003), effectiveness is found to be a component of serious game usability. This factor includes the time to complete the game and the memory space used in the game.

The result of multiple regression of learning gain on game usability criteria showed that the *p*-values of Content ($b = 0.01, p = 0.93$), Ease of Use ($\beta = -0.02, p = 0.87$), and Usefulness ($\beta = 0.08, p = 0.48$) are all greater than 0.05 level of confidence. Thus, aesthetics ($\beta = 0.227$), with an associated *p*-value of 0.025, was the only predictor of learning gain. Aesthetics accounts for 4% (Adj. R^2) in the variability of learning gain. The result is unlikely to have arisen from sampling error ($F(1,96) = 5.20, p < 0.05$).

DISCUSSION

The result of the experiment shows that the students have a considerable amount of knowledge on how to respond to disasters. It is interesting to note that 77% of the questions relating to earthquake response were answered correctly. This is explained by the fact that earthquake drills were conducted at school, local, and national levels at the time the study was conducted. This is in relation to the earthquake preparedness program of the government. This explains why the students have the highest percentage on earthquake items.

Meanwhile, students had the lowest percentage score on typhoon preparedness. On this item, students only had a passing mark on the pretest. This finding is unexpected considering that the Philippines is frequently devastated by typhoons. According to the Philippine Statistics Authority (2014), an average of nine typhoons visited the Philippines from 1993 to 2013. This explains the reason behind this unexpected result. Filipinos

are too attuned to typhoons to the extent that they do not mind preparing for them. In fact, it was reported that the strength of Typhoon Haiyan was underestimated by the locals, resulting to poor planning (Jibiki, Kure, Kuri, & Ono, 2016).

The result signals a need to conduct a study on the attitudes of Filipinos toward typhoons. This is not addressed in the current study. A game may be developed to assess the attitudes of Filipinos toward typhoons. The game may then respond depending on the assessed attitudes.

It is interesting to note that all test items increased following the intervention period. The test items for storm remained passing and surfaced as having the lowest score. Students had the highest learning on flood preparation. This is a good indication since flooding can be a consequence of other natural disasters, including typhoons. The overall learning gain of 35% means that students acquired 35 percentage points out of 100 percentage points that they could have gained from the pretest to posttest. This means that students acquired more than one-third of the possible points. Moreover, a learning gain of 30% is the defining minimum value at which the educational intervention could be regarded as effective (Hake, 1998; Prather, Rudolph, & Brissenden, 2009). In general, the game made it possible for students to know more about disaster preparedness.

After using the game, the posttest scores proved higher than the pretest scores. These indicate that students had positive learning gains. Further statistical tests confirmed that the differences in test items in fire, flood, tsunami, and volcanic eruption are significant. This shows that students learned to be more prepared in times of fire, flood, tsunami, and volcanic eruption. Furthermore, it also implies that the software can be utilized as an instructional material for disaster preparedness and risk reduction.

The evaluation of the usability design features of the game showed that students agreed that the information provided by the game is reliable. The students likewise favorably rated the software in terms of ease of use. According to the learners, it

is easy to learn how to play the game because all controls are functional. Students also perceived that they learned a lot from the game. The game helped them to understand natural disasters and how to respond appropriately. The result of open-ended questions showed that 26 respondents commented that the game is informative and helpful. This confirms the numerical rating on usefulness.

Meanwhile, they agreed to a lesser extent that the game is appealing. The responses of the 27 respondents on the open-ended question were in agreement that there is a need to improve the game's graphics. The nature of the participants may explain the findings. It is worth noting that the respondents of this study are information technology students who are knowledgeable in computer games. They may compare the game to other commercially-available games with better graphics and designs. Nonetheless, the evaluation of the respondents can serve as a basis to improve it in terms of screen layout, colors, and font sizes.

It was also revealed that six students enjoyed playing the game. They viewed the game as informative and helpful, as well as fun and enjoyable. The "fun" component of the game is not included in the evaluation. Future studies may include this factor in evaluating a game on disaster response. It is worth noting that students are also concerned with slow movement of the game character. The students recommended that the time to finish a task is not realistic. They were also concerned with the memory space it used when installed in a mobile device.

The result of the regression analysis revealed that it is justifiable to focus on the aesthetic components of the game. It was disclosed that aesthetics is the only predictor that could influence student learning in disaster response. Bringula & De Leon (2014) said that aesthetics is a "human" side design consideration. It is an "experiential" factor where "users have to use the software in order to judge the quality of the software" (Bringula & De Leon, 2014, p. 198). In short, this is the factor that users directly experience throughout the game.

Based on this finding, it is important that serious games developers consider the visual

content of the game in terms of its game objects, text layout, buttons, graphics, and colors. It is recommended that game objects be made clear. The text styles and sizes should be legible. Players must instinctively know the purpose of the buttons. The screen layout must fit the screen size of mobile devices. It is essential that colors blend the overall environment of the game. These aesthetic considerations can ensure the comfort of playing a serious game.

FUTURE RESEARCH DIRECTIONS

Aesthetics is found to be a significant predictor of learning in a mobile game. However, it accounts for only 4% of learning disaster response. In light of this finding, there are other usability design factors not considered in the study that might be investigated. The results of the experiment disclosed that fun and effectiveness were the two themes emerged from the open-ended questions. Future research may include these factors in the research instrument and quantitatively analyze their contributions in explaining the usability of the game. Informal interviews with students showed that the game can include more levels with different difficulties and surprises to capture the interest of the students. These design considerations will keep the students playing and will entice them to play the game again.

A study on different samples is also recommended. Children, who are among the most vulnerable sector of society, can be included as participants in future studies. The game can be utilized to teach them how to respond during natural disasters.

CONCLUSION

On the basis of these findings, the null hypothesis stating that the usability factors do not influence the knowledge of the participants in natural disaster response is partially rejected. It is also concluded

that the game was helpful in increasing the knowledge of the students to respond during fire, flood, tsunami, and volcanic eruption. It concluded that the game was not helpful during storm and earthquake situations. The game did not significantly contribute to student knowledge on responding to storms since they are already attuned to storms. They did not achieve a significant learning gain in earthquake test items because earthquake drills were conducted in local, institutional, and national levels prior to this study.

KEY TERMS AND DEFINITIONS

Aesthetics: A game attribute that relates to the overall visual design of a serious game.

Content: A game design feature that involves completeness and reliability of information provided by the game.

Disaster: An event that is caused by accidents or natural calamities that disrupts order and may result in damage of property or loss of life.

Ease of Use: A game design feature that measures the effort of the user in playing a game.

Mobile Game: A game that runs on any handheld portable device.

Serious Game: A type of game that is both entertaining and educational.

Usefulness: A game feature with a goal is to transfer knowledge or skills to its users.

Educational Technology and Intellectual Property

E**Lesley S. J. Farmer***California State University – Long Beach, USA*

INTRODUCTION

In today's digital world, leaders and other educators can manipulate a wide variety of information for authentic projects. In the process, everyone needs to acknowledge the idea creators and their intellectual property. As technologies have expanded, and their production has become more sophisticated, the legal regulations surrounding their use have become more complex. With the advent of interactive social media and increased resource sharing, as well as growth in distance learning opportunities, complying with the legal use of information technology can be daunting. In any case, leaders and other educators should be aware of the more important aspects of technology-related copyright laws and regulations. This chapter provides an overview of copyright law and fair use for educational research purposes.

LEGAL BACKGROUND

A central aspect of education is intellectual pursuit and the recognition of great minds. Yet teachers bemoan the rise in cheating, which technology facilitates. On their part, students have a more lax attitude about intellectual property. Particularly with media and crowdsourcing, which foster collaborate knowledge generation, identifying the originator of an idea can be difficult to ascertain. Furthermore, the informational content itself may be dynamic so that the authorship and copyright may change over time.

Although intellectual property is sometimes used interchangeably with copyright, the former is

a broader concept. Copyright protects creative and original ideas that are recorded in tangible form. Other U. S. intellectual property laws deal with trademarks, patents, trade secrets, and licenses.

Copyright laws seek solutions to give authors fair compensation for sharing their work. Begun as a way to give scientists and inventors lead time to prevent others from using their work without permission, copyright laws in the United States have become more far-ranging, both in terms of expanded formats as well as issues of authorship and access. According to current law, the copyright owner has the exclusive right, and can authorize others, to reproduce, distribute, display, publicly perform, and make derivative works based on the original work. The duration of the copyright term has lengthened over the years, starting from a length of 28 years (as established in 1790) to 70 years after the death of the author, according to the 1998 Act.

Publishing has also impacted copyright over time. Reporters increasingly get personal credit and remuneration for their contributions, which historically were considered solely work for hire. Publishers create copyright agreements to cover authorship rights based on format. Multimedia copyright laws can be very specific: restricting resizing or other image manipulation, stipulating the length of music or video that can be copied legitimately. Fortunately, education falls under the umbrella of Fair Use, so restrictions are loosened up a bit in order to support personal research.

The chief statute driving copyright law is the Copyright Act of 1976, which became effective in 1978. Several factors were included for the first time in this piece of legislation: a codification of

fair use, the right for an author to receive copyright for an unpublished work, and the divisibility of authors' rights. The Act includes definitions, delineates what is copyrightable, and describes copyright rights and limitations.

The Digital Millennium Copyright Act (DMCA) was added to the Act in 1998, largely to conform to international treaties (note that no international copyright law exists) that dealt with technological issues, particularly online material. DMCA limits database company liability, and addresses digital preservation.

Educators and leaders also need to know about the 2002 Technology, Education, and Copyright Harmonization (TEACH) Act, which impacts copyright usage in distance education or in cases where digital information is transmitted as a supplement face-to-face instruction. Displays and performances can be disseminated only for the period of the course and only to those students who are enrolled in the course. Likewise, if teachers copy an article for a face-to-face class, then they can link to the same article online, depending on the magazine database license agreement. A better solution is for the teacher to provide the citation, and ask the students to access the article themselves from the library's database collection. However, the teacher should *not* download the whole magazine issue just because it is technically possible; that action probably does not comply with copyright law.

Other laws exist to support copyright law such as anti-piracy. For instance, the 1997 No Electronic Theft Act expands criminal prosecution of copyright infringements to individuals who do not benefit commercially. The Family and Entertainment Copyright Act of 2005, updated and absorbed the 1997 Act about theft, and also addressed artists' rights.

Particularly with the advent of social media in which students might produce and disseminate information publicly, copyright applications are stricter. A few examples of technology-relevant copyright practices follow.

- Images should not be resized, cropped, or changed in context without explicit permission.
- Photos of recognizable people require written permission if they are to be broadcast.
- Scanning or digitizing work is considered reproducing it, and requires prior permission if shared publicly. Other rights may be covered by patent law, such as copying code.
- Music and video downloads can be very problematic. It is wisest to use pre-approved sites such as iTunes.
- Computer program appearance, graphics and sound may be protected from copying, depending on the company's licensing agreements.
- Slander and libel can occur on social networking sites such as MySpace and Facebook; students might not realize that they can be held legally responsible for their comments, and even arrested and prosecuted.
- Information about health and legal issues should include a disclaimer so the author is not held legally responsible in case the reader uses that information and experiences negative results.
- Each database aggregator and disseminator (such as video streaming) has a unique licensing agreement that covers copyright issues. A good rule of thumb is to apply the most conservative guidelines in order to avoid case-by-case decisions.

Further complicating matters, different countries have different copyright guidelines, so information accessed from around the world may be subject to conflicting laws. International aspects also impact copyright in several ways. At present, few copyright laws exist. How, then, are royalties handled when publishers are international or offer translations of works? They are done by international treaties or agreements, usually on a

case-by-case basis. Right now, Disney licenses some merchandise abroad, which products are not allowed in the U.S. because of copyright restrictions; foreign entities can sell them to U.S. buyers, who cannot buy the items stateside. Such inequities need to be addressed.

This situation is exacerbated in light of transnational social networking sites such as Facebook and Google, who are reluctant to comply with the most stringent regulations when other countries may have laxer laws. The International Copyright Act of 1891 was the first step in extending copyright to works of foreign nationals – of selected countries. The World Intellectual Property Organization (WIPO), established in 1967 under the auspices of UNESCO, serves as a global forum to address issues of intellectual property services, policy, information and cooperation. Currently, they are discussing the need for libraries to be able to provide all of their users with access to information, particularly to facilitate countries' economic development (IFLA, 2014).

Legal cases test the boundaries of existing copyright law. The U.S. Copyright Office's Fair Use Index (<http://www.copyright.gov/fair-use/>) provides searchable summaries of major fair use decisions. For instance, *Authors Guild, Inc. v. Google Inc.*, No. 13-4829-cv (2d Cir. Oct. 16, 2015) contested Google's to digitally duplicate books from library collections. The court defended Google's practice as covered under Fair Use because the process was transformative: the search function added value, and the materials were for libraries. Nor did the digitized clips jeopardize market value. Similarly, in *Authors Guild, Inc. vs. HathiTrust*, 755 F. 3d 87, 90-91 (2d Cir. 2014), the court upheld the practice of creating read-aloud versions of resources so they would be accessible for individuals with vision impairments; the decision was based on the Americans with Disabilities Act. On the other hand, when publishing houses sued Georgia State University for posting unlicensed works for students to access, even after using a fair use checklist;

the university was found at fault for not complying with licensing agreements as they impacted copyright (*Cambridge University Press v. Mark P. Becker* No. 1:08-cv-01425-ODE (N.D. Ga. March 21, 2016)).

As seen above, copyright law changes over time as it tries to respond to changes in technology and societal behaviors. Every three years, the Library of Congress makes decisions about copyright waivers under DMCA; for instance, DVD snippets can be "ripped" for educational purposes, and electronic literary works may be "cracked" to enable read-aloud functionality for individuals with visual impairments (Hobbs, 2016). Other copyright issues, such as the appropriate copyright handling of orphaned works (where the author cannot be identified or contacted), remain. Crowdsourced materials also constitute a copyright headache, and one can only imagine how future formats and content interaction will impact and maybe redefine copyright.

Derivative works gains another dimension in the copyright world as individuals transform existing recorded (thus copyrighted) materials (Ahmeti, 2015). The copyright holder may create derivative works such as adaptations, revisions, translations, extensive excerpts, and different formats of the same work; if others want to make a derivative work, they must ask for permission from the holder. However, if a person *transforms* the work, then copyright permission is not needed; transformation requires adding something new for a further or different purpose rather than a substitution of the original work; example include parodies, mash-ups, remixing. While sampling may be transformative, it should be noted that in the music world, digital sampling is very restrictive.

When in doubt, users should act conservatively. On the other hand, these copyright issues can overwhelm educators, who then may be reluctant to incorporate digital sources, in particular, for fear of the "copyright police." As a result, learners may have little access to valuable open education materials.

FAIR USE

Fortunately, educational institutions enjoy more freedom in the use of copyrighted materials because of the intent of that use: teaching and personal research without market compensation. These fair use exemptions are listed in Section 107 of 17 United States Code 106:

1. The purpose and character of the use, including whether such use is of commercial;
2. Nature or is for nonprofit educational purposes;
3. The nature of the copyrighted work;
4. Amount and substantiality of the portion used in relation to the copyrighted work as a whole; and
5. The effect of the use upon the potential market for or value of the copyrighted work.

The expansion of digital resource has further complicated copyright laws and Fair Use. The ease and speed of digital duplication can tempt the most honest user. Especially when software “suites” facilitate repurposing of information (such as turning a PowerPoint into an outline word processed document), it can be difficult to explain how to use digital materials within copyright limits. How does format define information? How does multimedia incorporation change the nature and intellectual property of each information element? These issues can lead to valuable learning moments during which students can understand the nuanced nature of digital information. The National Council of Teachers of English has developed a code of best practices in fair use for media literacy education, which can serve as a useful set of guidelines (<http://www.ncte.org/positions/statements/fairusemedialiteracy>).

Certainly, students and teachers alike need to cite sources accurate to credit the original creators, but it is no substitute for asking permission. Basically, asking permission requires finding the author of the work, identifying the specific information to be used (full citation, including

which section of the document), the purpose of the use, and the extent of use (e.g., how, where and frequency). Copyright clearinghouses (e.g., <http://www.copyright.com>) can also help users obtain permission.

Fortunately, user-friendly guidelines about fair use are available. The American Library Association for Information Technology Policy has developed copyright educational tools that focus on copyright and fair use: <http://www.ala.org/advocacy/pp/pub/copyright>. The Copyright Advisory Office of Columbia University Libraries’ Information Services has developed a useful fair use checklist that can help the education community respect intellectual property while researching and generating ideas: <https://copyright.columbia.edu/basics/fair-use/fair-use-checklist.html>.

PROJECT CHECKLIST

As multimedia and digital resources are incorporated into presentations, particularly as these products are broadcast online, the school community needs to follow more stringent copyright guidelines. The Washington State Library (2008) has developed a checklist of factors to consider when thinking about using and publishing information. Their first point is probably the most salient: ownership of physical and digital objects doesn’t guarantee use rights.

- Who owns the material? Have you made a good faith effort to find the owner? Who controls access to the physical items? Who will control access to the digital items?
- Are there written agreements as to construction, ownership, and access to the digital collections?
- Determine copyright and permissions status; are the materials owned outright? Can the rights to publish the materials digitally be obtained?
- What percentage of the materials will need research or requests for permissions? What

will be the added cost of devoting staff time to obtaining permissions?

- Is the material in the public domain or covered by copyright that your organization has legally obtained?
- Remember, any original student work cannot be digitized or published without a signed permission form from the student or their guardian if they are a minor.
- Address copyright, permission to copy on your own digital site. Post a statement to guide use of materials on your digital Web site.
- Provide contact information for users of your Web site.

THE CREATIVE COMMONS

A growing interest in the creative “information commons” reflects a philosophy that “information yearns to be free” and that accessible information leads to expanded discourse, knowledge and progress. Public domain documents have exemplified this philosophy for over a century, and government publications carry on this tradition in the spirit of civic engagement.

A welcome alternative is the Creative Commons (<http://www.creativecommons.org>), which enables people to upload and share data with the understanding that any use requires cited acknowledgment, and any changes to the data also need to be uploaded and cited within the Creative Commons. This proactive strategy recognizes the benefits of collaborative knowledge building. In 2005 the International Federation of Library Associations and Institutions (IFLA) called upon the World Summit on the Information Society Summit to promote a global Information Commons where all people could access and disseminate information without restrictions. Two main approaches to the creative commons have emerged: 1) contributing and modifying original information, and 2) facilitating the *sharing* of information.

The idea of a creative commons can be expanded across systems, disciplines, even national boundaries. Creative Commons provides an extensive directory of federated repositories (http://wiki.creativecommons.org/Content_Directories). One of the advantages of federated collaborations is that each site typically controls copyright and licensing issues. Nevertheless, these consortia initiatives require careful, thorough planning, not only in terms of technical requirements but also in terms of fiscal and governance issues.

A recent development related to the Creative Commons is the Open Textbook Initiative. In an effort to make textbooks more affordable, the Higher Educational Opportunity Act of 2008 supported the development of open textbooks. Textbook publishers, such as Flat World Knowledge, offer free online access to textbooks under a Creative Commons license, and low-cost fees for printing copies. In addition, these textbooks are often repurposed so that instructors can essentially create customized texts for their courses. Faculty are more apt to access such materials through repositories than publishers, such as Cool4Ed, Curriki, and OpenLearn. While open textbooks certainly attracts students, some instructors are concerned that materials have not been adequately reviewed so might not be high quality. On their part, some authors are not so keen on this practice because they get little or no fiscal remuneration for the materials they create. Instead, they must be satisfied with possible increase in visibility and reputation, and derive satisfaction from contributing to the field in a timely manner.

Similarly, “open source” is a growing approach to software development, which impacts intellectual property rights, mainly in the areas of patents and licensing. The term emerged with Netscape’s code, which was openly released in 2006 for others to use freely. At this point, the largest repository of open source code, SourceForge, has over than three million registered users. Open source code has been the basis for many social networking applications such as wikis and blogs.

TECHNOLOGY-BASED INFORMATION PACKAGES

Individuals and institutions routinely “package” information together as a way to synthesize the best resources for their clientele. For instance, course “readers” have been a mainstay for years. Copyright permission has always been a part of that production process. Several general copyright issues loom when dealing with technology aspects of packaged information. As libraries and other educational entities jump on the curation band wagon, especially in the digital realm, they need to be aware of copyright issues.

- **Content:** Does the entity have permission to copy, download, digitize, modify, excerpt, or package information? What is the copyright for each document? What limitations exist on such practices: e.g., length of time to keep the copy, number of copies (sometimes within a specified timeframe), extent of copying (such as percentage of the entire work), access rights, purpose limitations (such as referral vs. personal research vs. resale), format.
- **Format:** Packaging information, such as software installation instructions, for internal use, is a much different issue than scanning published cartoons for a public website. Even if the entity gets permission to copy an image, that permission might not extend to resizing or cropping the image. Copyright owners might not permit content to be reformatted or repurposed with reason, since changing context can result in different interpretations of the information. Likewise, pinning up candid student pictures in the faculty mail room requires a different level of permission than broadcasting those same pictures on the Internet, particularly if any under-age students are shown. Indeed, because of stalking and other criminal behaviors, few institutions show captioned pictures of their staff, particularly in online environments.

- **Liability:** Entities need to read licensing agreements carefully to make sure that their packaging efforts comply with the legal language. Users need equitable access, proper authorization, and confidentiality; moreover, no profits can be incurred (Farb & Riggio, 2004). Once entities start to extract and synthesize information, even with permission, they stand to risk being sued. For instance, health information might be followed by some user with unpleasant results. Especially in the areas of law and health, entities need to make sure that they post a disclaimer that they are not legal or health professionals (unless so licensed). Even the software used to package information is likely to entail legal right for its use, particularly if the product is web-based and disseminated externally. The North Carolina State Library Web Portal Collection Development Policy addresses a number of these issues (<http://www.digitalnc.org/about/policies/digitization-guidelines/>).

In addition, specific types of information packages have unique copyright implications, as detailed here.

Courseware

Most campuses now use learning management systems or courseware as a means to access course materials or facilitate communication. Faculty may spend hundreds of hours developing and implementing their course materials: creating their own content, selecting and linking other existing resources, sequencing content, facilitating student interaction, and providing feedback. Who owns the content?

Generally, their affiliated institution owns the course and its content as part of the faculty contract; it is considered work for hire. However, each institution or educational system determines intellectual property and accompanying copyright agreements. Can the faculty make money inde-

pendently from that course material? Usually only if they transform the existing work. Adding an Amazon link to the instructor's campus website so students can buy an instructor's publications can be asking for trouble. Can another faculty member copy the course entirely, and teach with it? They need permission from the copyright holder, which is probably the campus administration; faculty should ask about the appropriate protocol ahead of time – and administration should inform all faculty about course intellectual property rights from the start. The American Association of University Professors Copyright, Distance Ed & Intellectual Property does a good job of explaining implications of technology for teaching and learning, and provides sources to help faculty protect their intellectual property (<https://www.aaup.org/issues/copyright-distance-ed-intellectual-property>).

What about copyright and fair use of MOOCs (Massive Open Online Courseware)? Institutions anticipate unlimited participation and open access; however, they are increasingly likely to include carefully worded licensing agreements even though they provide free access to students. In other words, one may look but not copy; fair use might not apply to non-MOOC educators. To be safe, instructors should simply link to the original material or online course rather than download or copy it (Hui-Wen & Chao-Chen, 2012).

Repositories

Increasingly, institutions and organizations are developing digital repositories, either storing data or storing the documents themselves. In both cases, these services manage and disseminate digital resources. The scope of repositories can range from a single program to international consortia. The value of repositories lies in the quality of use of their content, so identifying desired kinds of documents and collecting high-quality materials are key functions. Of special interest now are repositories of data sets; U.S. federal agencies now require a data management plan as part of their grant proposals, so most academic libraries

either establish an in-house repository or join a data management consortium. Major technology management issues of a repository follow:

- Maintaining the data without damage or alteration: storage and security requirements.
- Providing “physical” access to the data, including extracting of it from the archive: authentication, verification, identification, metadata harvesting software.
- Ensuring that the user can understand and interpret the data: display/rendering software and preservation planning.
- Ensuring long-term stability: technology planning and data maintenance (Wheatley, 2004).

In structuring repositories, entities need to consider three layers: storage, database, and application, each of which may have copyright implications. The Academic and Research Libraries of the American Library Association developed an institutional repository SPEC toolkit to help librarians with policies and procedures (<http://www.arl.org/storage/documents/publications/repository-services-report-jan09.pdf>).

One promising practice in digitizing materials is systemwide technology initiatives, usually in the form of federated repositories of archival materials. DSpace (<http://www.DSpace.org>) is an Open Archive Initiative that provides guidelines for digitizing, cataloging, storing, and disseminating unique digital sources. This open source solution emphasizes the need for technical expertise and planning. Nevertheless, the *content within* the repository still needs copyright oversight. Duranceau and Kriegsman provide guidance on open access policies for institutional repositories (http://www.ala.org/alcts/sites/ala.org.alcts/files/content/resources/papers/ir_ch05_.pdf).

Knowledge management (KM) consists of managing the knowledge of an organization, usually collecting, storing, organizing, and disseminating explicit information such as documents with the intent that others will use that

information: an internal repository. Particularly in today's society where in-house knowledge may be proprietary and employees may leave after a short time, making tacit knowledge explicit through the use of a knowledge management system offers an effective way to coalesce expertise. Because they are internal, such KM repositories normally do not require copyright permission, although institutions should set up policies and procedures that delineate levels of access and authorization protocols. As some of the documents may be permitted to be access externally, dealing with copyright permissions from the start is a good practice.

E-Publishing

For decades, in order to inform their constituents, institutions and organizations have created documents for their own members and for the public. These might be as simple as a guide to the library or as sophisticated as a peer-reviewed journal. Be it an original document or a compilation, copyright law must be observed.

For example, Stanford University Library's HighWire Press publishes almost a thousand e-journals. The press prides itself in its efforts to incorporate multimedia, hyperlinks, interactivity, and powerful search engines. Although they publish some free online articles, the press hosts digital content on behalf of many publishers, each of which has specific terms of use. HighWire's notice states: "Unless explicitly stated otherwise, content on HighWire's publishing platform, including content accessible without charge, cannot be copied, re-purposed, displayed on other websites, reprinted, redistributed, entered into a database, modified, used to create derivative works or otherwise re-used without the specific permission of its publisher" (<http://highwire.stanford.edu/about/terms-of-use.dtl>).

In a few cases, one of the impetuses is financial gain, but for the majority of e-publishers the goal is dissemination of information on topics of interest to their clientele. To this end, open access journals have become quite attractive: they are

relatively inexpensive to create (except for labor costs of editing and layout) and disseminate, can include digital features not available in print format such as sound, and may be more timely to publish than print versions. The Scholarly Publishing and Academic Resources Coalition (SPARC) (<http://www.arl.org/sparc>), founded in 1998, exemplifies a collaborative library approach to disseminating research. Internationally, the Budapest Open Access Initiative (2002) asserts that

Removing access barriers to this literature will accelerate research, enrich education, share the learning of the rich with the poor and the poor with the rich, make this literature as useful as it can be, and lay the foundation for uniting humanity in a common intellectual conversation and quest for knowledge.

On the other hand, copyright issues connected with maintaining a permanent collection of the e-publications may be overlooked. Furthermore, if indexing services do not receive a copy of the journal, then access to the information will become even more limited. The Association of College and Research Libraries provides a scholarly communication toolkit, which specifically supports a more open system of digital scholarship (http://acrl.ala.org/scholcomm/?page_id=42). Charles W. Bailey, Jr. maintains the most extensive overview about digital scholarship publications (<http://www.digital-scholarship.org/about/overview.htm>).

Linking Sources

The "off-the-street" online user would like a single-stop searching tool that would link all relevant material: primary sources, secondary sources, print, web-based, audiovisual. Increasingly, libraries are using "discovery" tools that approximate this process; a first search typically results in a list of articles and a list of books and media, with a number of additional criteria (e.g., format, date, language, full-text, etc.) to filter results. The new cataloging standards are built on

the Functional Requirements for Bibliographic Records (FRBR) conceptual model, which facilitates linking individual data elements of a source with other sources (Howarth, 2012). The Open Linked Data Project further extends this idea through the semantic web. While an exhaustive one-stop tool is probably not feasible in the near future (despite Google's intention), smaller-scale reference linking has become an attractive way to add value to information, and facilitate information services. There are several ways to link sources:

- Between citations (e.g., databases)
- Within sources (e.g., hyperlinks)
- Between sources and applications (e.g., course management systems)
- Between sources and services (e.g., e-reserves)

Usually, metadata provides the basis for these actions. Digital Object Identifiers (DOI) provide an international standards-based “system for persistent and actionable identification and interoperable exchange of managed information on digital networks” (<http://www.doi.org>).
